CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C., December 18, 1950 3:00 P.M. (E,S.T.)

December 1950

ACREAGE AND PRODUCTION OF CROPS IN 1950.

Crop production in 1950 was the third largest of record. This output exceeds the average of the previous 8 years, the most productive period in American agriculture. Farmers attained this desirable result despite reductions in acreage of several important crops and a growing season that had many unfavorable aspects: The composite yield per acre in 1950 is the second-best of record. A prolonged fall season for maturing and harvesting crops helped improve both quantity and quality of the outturn.

The aggregate volume of crop production in 1950 is 126 percent of the 1923-32 average. This index is well below the 137.5 percent in 1948 and 132 percent in 1949, but exceeds that of any other season. It was attained despite a smaller total harvested acreage of 52 principal crops than in any year since 1942. The composite yield index of 142 percent, however, is second only to the 151 percent in 1948. though virtually the same as in 1949.

Few crops contributed record outturns to this relatively large 1950 total -only soybeans, sorghum grain, sugar beets and red clover seed. The corn crop of 3,131 million bushels slightly exceeds recent forecasts and is fourth-largest of record. Others in this class of very large crops are oats, all hay, rice, potatoes, popcorn, tobacco, cranberries, and alfalfa and sweet clover seeds. Larger than average crops of flaxseed, sorghum silage, peanuts, sugarcane for sugar and seed, hops, timothy seed, apples, pears, cherries, citrus fruits and truck crops were harvested. Only slightly below average were wheat, barley, dry beans, sweetpotatoes, alsike clover and lespedeza seed, maple products, and pecans. Cotton and cottonseed, peaches, and apricots were relatively small crops, while rye, buckwheat, sorghum forage, dry peas, compeas for peas, velvetbeans, broomcorn, sergo and sugarcane sirup were among those with very small outturns, ranging from about onehalf to two-thirds average.

The planting season for 1950 crops began favorably in the fall of 1949; but developed unsatisfactorily in the spring over most of the main agricultural area. Winter wheat was sown under mostly favorable conditions, but in the southern and central Great Plains it faced a steadily increasing hazard from dry soils and insects until near harvest time. The winter was severe in the Pacific Northwest, but snow cover was a saving factor. Elsewhere the winter was mild and, because of lack of snow cover in much of the eastern North Central wheat area, stands were thinned by alternate freezing and thawing. Spring was slow to arrive and cool, wet wea'ther persisted in areas where spring seeding of grains is important. Seeding was delayed far past usual dates, ranging to as much as 6 to 8 weeks late in North Dakota, It was only by the most persistent efforts of farmers that so large a proportion of intended acreages of spring grains was actually sown. Planting of corn and soybeans started later than usual, but was completed rapidly in the short periods of favorable weather in May and early June. Sorghum planting was delayed by dry topsoils in the Great Plains, and some cotton planting and tobacco transplanting was delayed by wet soils, but such crops as rice, peanuts and sugar beets were planted under favorable conditions.

During the growing season the usual extreme temperatures failed to appear, permitting spring grains and meadows to develop satisfactorily, though rains at inopportune times delayed harvesting and caused some spoilage.

CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C., December 18, 1950

December 1950 3:00 P.M. (E.S.T.) However, these conditions were unfavorable for cotton, fostering development of weevils and worms, and for corn, retarding its development but lessening the cornborer hazard. Concern mounted over the retarded development of crops and the approaching frost hazard, but providentially warm; dry weather came near the end of September and continued through October into November. The outcome was satifactory maturity and harvest of most of the latest fields, leading to what is termed a "miracle season" in hardest-hit North Dakota. Much less corn than expected was frosted and became "soft corn", although in some northern areas salvage operations were necessary after August and September frosts.

The 1950 season emphasized the importance of farm mechanization, as power machinery enabled producers to wait out periods of adverse weather and make rapid progress with field preparation, planting, cultivation, or harvest when condtiions became favorable. Labor supplies were generally adequate. Fertilizers were used to, an increased extent, but supplies of some kinds did not meet all demands. Transportation facilities were nearly adequate, although a shortage of boxcars became apparent toward the end of grain harvest. Augmented storage facilities were adequate for both carryover and new crop grains.

The acreage upon which the 52 principal crops were planted or growing in 1950 totaled nearly 358 million acres, about 12 million less than in 1949. This acreage is 1 percent more than in 1946 and slightly more than in 1945, but is less than in other years since 1942. The largest comparable acreage was 375.5 million in 1932. Compared with 1949, heavy reductions were made in some crops under allotment programs -- cotton, more than 9 million acres; corn, nearly 4 million; winter wheat, ever 9 million; spring wheat, over 4 million; rice and dry beans, each ½ million-also more than a million acres in flaxseed. On the other hand, acreages of oats and barley were each increased over 2 million, soybeans over 3 million, sorghums nearly 5 million, rye less than \frac{1}{2} million, sugar beets \frac{1}{4} million and all hay by 2 3/4 million acres. Increases in oats and barley might have been larger if weather had been less adverse at seeding time. Sorghums were planted on much land previously used for cotton and on some abandoned winter wheat acreage.

Harvested acreages of the principal crops amounted to about 341 million acres, the smallest total since 1942. It is nearly 16 million acres less than the relatively large 1949 total and close to 21 million acres less than the 361.8 million acres harvested in 1932, the largest of record. The changes from last year in aggregate acreages, by regions, tend to reflect the effects of allotment programs as well as the kind of crop season. The North Atlantic region harvested about the same relatively low total as in 1949, less than 2 percent above its record low of 1947. In the North Central regions, which annually accounts for more than half of the country's harvested acreage, the total of 193.6 million acres is 3.8 million acres less than the relatively high 1949 total. The South Atlantic region dropped to about 25 million acres, 1.3 million less than in 1949 and 0.5 million below the previous record low of 1948. A sharp drop to 66.7 million acres harvested in the South Central region makes that acreage 9.3 million less than in 1949 and much lower than any other year of record. The Western region dropped to 39.1 million acres, 1.5 million less than last year, but still relatively high. Nevada barely topped a record set last year and Montana also set a new high mark.

Acreage losses, as represented by the computed difference between planted and harvested acreages, amounted to about 16 3/4 million acres. This is much larger than acreage losses in any of the last 9 years and largest since 1939.

UNITED STATES DEPARTMENT OF AGRICULTURE

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D.C., December 18, 1950 3:00 P.M. (E.S.T.)

December 1950 More than half of the total is abandoned winter wheat acreage, mostly in the Great Plains, which was larger than in any of the Past 12 years. Acreage losses were heavier than last year in cotton, due to weevils and weather, and in oats, largely due to greenbugs in the Southwest. For most other major crops there were no unusual losses. Adverse factors were chiefly reflected in lowered yields or increased harvesting losses, although frosts caused relatively heavy damage to some fruits in the Northwest and Southeast and to some vegetable crops.

Yields per acre were relatively high, with prospects improving as the season progressed. Wheat and broomcorn yielded below average, though the wheat yield was higher than in 1949. For all other major crops, yields were higher than average. Only a few yields were lower than in 1949 -- among them corn, buckwheat, sorghum grain and forage, cotton, dry beans, soybeans, sorgo sirup and sugar beets. New high yield marks were set for rice, tobacco, potatoes and sweetnotatoes. Combined into a composite yield, the all-crop index is 142 percent of the 1923-32 average, barely topping that of 1949 and exceeded only by the 151 percent in 1948.

Over 158.4 million tons of the 8 grains were harvested in 1950, a total exceeded only 3 times -- by 2 to 3 percent in 1946 and 1949 and by the record 180.5 million tons in 1948. Food grains make up nearly 33.5 million tons of this year's total which was 3.5 million less than last year and the smallest tonnage in 7 years, but larger than in any year before 1944. The wheat crop of 1,027 million bushels is virtually up to average; the 38 million bags of rice is the third-largest crop of record; the 23 million bushels of rye is nearly a third below average, while the 4.7 million bushels of buckwheat is about a third below average and smallest of record.

The third-largest tonnage of feed grains was harvested in 1950. The 125 million ton total is nearly a million tons less than in 1949 and a tenth below the 1948 record of 138 million. Included in the total are relatively large outturns of 3,131 million bushels of corn and 1,465 million bushels of oats, a below-average barley crop of 301 million bushels, but a record-smashing sorghum grain production of 2372 million bushels. Including fairly large carryover stocks, the farm supply of feed grains for the 1950-51 season is third-largest of record. Sumplies of hay, including the large new cut of 107 million tons and an average carryover, are the most abundant in history per animal unit. The new hay crop includes a record quantity of alfalfa hay. Furthermore, the mild fall permitted prolonged excellent grazing of pastures, meadows and fields, thus limiting hay consumption. All areas appear to have ample roughage supplies, although much of the southern part of the western range area reports poor prospects for winter grazing.

Oilseed production of 14.7 million tons is the third-largest intonnage, only 6 percent less than the record 1949 tonnage, but more than a fourth above average, Soybeans account for well over half of the 1950 tonnage, but their sharp increase does not offset decreases from last year in flaxseed and cottonseed. The tonnage of neanuts is larger than either last year or average. Cottonseed tonnage is expected to be less than two-thirds that of 1949 and a sixth below average. current estimate of 9,884,000 bales of cotton in 1950 makes this one of 8 crops below 10 million bales in the last 50 years.

The third largest tobacco crop, also the third in history to exceed 2 billion pounds, was harvested this season. The 1950 crop is larger than in 1949, even though the acreage was smaller. This results from a new record yield of 1,277

CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C., December 18, 1950

December 1950 3:00 Polis (EsSella) pounds per acre. A big increase in flue-cured types more than offset decreases in burley, firs-cured and dark air-cured types, with slightly more cigar tobaccos also than in 1949. The output of sorgo sirup is only slightly larger than the record small 1949 crop, while that of sugarcane sirup is the smallest of record. Sugarcane for sugar is a relatively large crop, while the 1950 sugar beet tonnage is the largest ever produced in this country. Sugar production from boets and canc, raw basis, is expected to total almost 2.6 million tons, nearly a quarter more than in 1949. Although the 1950 potato acreago was down to about two-thirds average and the smallest since 1876, a record yield of 238 bushels per acre resulted in a production exceeded only 3 times previously. A new record yield was obtained by sweetpotato growers also, but because of a small acreage total production was slightly below average, although more than in 1949.

Supplies of the 6 major hay-crop seeds are considerably larger than last year or average. A record crop of rod clover seed, very large outturns of alfalfa, sweetclover and timethy, but below-average production of alsike clover and lespedeze seeds total to about 610 million pounds of thresher-run seed. This total is a tenth larger than the 1949 output and more than a fourth above average. In addition carryover stocks are much larger than a year ago and are nearly average. Harvest of most of these seeds began later than usual and movement from farms is also slower than usual. Quality averages fairly good. Cleaning losses are expected to be heavier than average.

More than 9 million tons of the 25 truck crops for fresh market were harveste in 1950, a tonnage second only to that of 1946 and a fifth above average. The portion of the tennage produced which was not marketed, however, was largest of record, with cabbage, lettuce, watermelons, onions, carrots and celery accounting for the bulk of ite Of 16 vegetables produced in larger quantity than last year, cabbage accounted for more than one-third of the increase in tennage, with onions, lettuce and carrots also in much larger supply. Of 9 vegetables showing decreases in tomage, the largest decreases were in tomatocs, spinach, snap beans, green peas and cucumbers. For processing, about 5.3 million tons of the 11 truck crops covered by estimates were produced. This total quantity used for commercial canning. freezing, pickling and other forms of processing (except dehydration) is slightly loss than in 1949, but slightly above averages. Harvested acreages of asparagus, beets for canning, and pimientos were largest of record. Yield records were set for lima beans, cabbage for kraut, and tomatoes. Wisconsin, California and Minnesota led in acreage, while California led in production with about a fifth of the total tonnage and value of vegetables for processing.

The 1950 crop of deciduous fruits totaled 8.5 million tons, 1.2 million tons less than in 1949 and 1/2 million loss than average. Production this year varied considerably by areas due to winter injury and late spring freezes in some States. A decline from a year ago was recorded for all major deciduous fruits except apricots and sour cherries, which were above 1949. Compared with average, apples were one-tenth more, peaches one-fourth loss, pears slightly more, grapes slightly less, prunes one-fourth less, apricots a seventh less, and cherries about one-third more. The 1950-1951 citrus crop totals 7.1 million tons, up 10 percent from 1949 and 7 percent from average. Tree nut crops totaled 163 thousand tons, -- 21 percent less than the large crop of 1949, but 6 percent above average. The economic abandonment of fruit and nut crops this year was light, and much less then a year ago

CROP REPORT 85 01

CROP REPORTING BOARD

Washington, D. C., Iccemier 18, 1950 December 1950 3:00 P.M. (E.S.I.)

CORN: The 1950 corn crop, estimated at 3,131 million bushels, is 7 percent below the 1949 production of 3,379 million bushels, but 8 percent above the 1939-48 average of 2,901 million bushels. Fresent estimates of all corn include, in addition to corn for grain, the grain equivalent production of corn harvested for silage, forage, hogging, and grazing. The 1950 production of corn for grain is estimated at 2,345 million bushels, a decline of 270 million bushels from last year.

The decline in this year's total production from 1949 is the result of both reduced acreage and smaller yields per acre. The 1950 acreage for harvest, 83.3 million acres, was the lowest since 1894, reflecting the effects of acreage allotments in the higher yielding commercial corn areas. The average 1950 yield per acre of 37.6 bushels was 1.2 bushels below last year. In the important North Central States the indicated yield of 42.6 bushels was 1.5 bushels below last year. Of the 1950 harvested acreage, 89 percent was harvested for grain, 6 percent for silage, and 5 percent was used as forage or for hogging and grazing. Early frosts in northern areas resulted in some acreage originally intended for grain being diverted to other purposes. Despite considerable adverse weather during the 1950 season, the percent of the planted acreage abandoned, 1.3 percent, was about the same as last year. Average abandonment is 2.0 percent.

In the important North Central States, weather conditions were only fair during the 1950 season. Plantings were started several weeks later than usual, due both to adverse weather and to the practice of delaying plantings in order to minimize the threat of corn borer infestation. Corn borer damage, although heavy in localized areas, was considerably lighter this year than in 1949. Cool weather which prevailed during the planting season continued throughout most of the summer, tending, to retard the development of the crop. Farlier than usual frosts occurred in parts of the Corn Belt, particularly in the northernmost areas - as early as August in some local areas. However, October weather was very favorable for drying out the corn that had been frosted before reaching maturity. Freezing temperatures which followed the warm October period were beneficial in hastening maturity of the portion of the crop which had not been frosted. Because of the lateness of this year's crop, harvesting operations were held up to permit further maturing of grain corn. As a result, many fields were unharvested when late November snow storms occurred in parts of the Corn Belt; these storms caused some breaking of stalks and further delayed harvest. Although there is still considerable high moisture content corn in parts of the Corn Belt, these quantities are not as great as expected earlier in the season. There is considerable light chaffy corn, particularly in northern areas of Iowa and in central Minnesota.

In the Northeastern States, the 1950 season was moderately favorable for corn, average yields being slightly below 1949. Cool nights delayed progress during the summer months. Killing frosts occurred in some areas during the latter part of September, causing considerable damage both to grain and silage corn. A large amount of silage corn was cut before reaching maturity.

In the South Atlantic States, record yields were realized in all States except West Virginia and Georgia. The West Virginia crop was retarded by heavy rains during the growing season. In Georgia, extremely dry June and July weather reduced corn yields considerably in the southeastern part of the State.

Weather conditions were generally favorable during the 1950 season in most of the South Central States. However, the Kentucky crop was adversely affected, particularly in lowlands, by heavy summer rains and cool weather. In Texas, cool dry weather delayed planting and early growth. However, the Texas crop responded to later favorable weather and fair yields were attained. Yields for the group of States as a whole averaged 0.7 bushels above 1949.

UNITED STATES DEPARTMENT OF AGRICULTURE

CROP REPORT

BUREAU OF AGRICULTURAL . ECONOMICS

Washington, D. C., December 18, 1950

CROP REPORTING BOARD

December 1950.

The the Western State of State o In the Western States, yields on irrigated land were very good but dryland yields were only fair. Indicated yields for this area were about I bushel above last year. October weather was unusually favorable for maturing and drying corn. In Colorado, the leading corn producing State in the Western group, the indicated yield of 24.0 bushels per acre compares with last year's record yield of 25.5 bushels and the average of 18.0 bushels.

ALL WHEAT: The aggregate production of all wheat for the country as a whole during 1950 is estimated at 1,027 million bushels, up slightly from the October 1 preliminary estimate. This compares with 1,141 million bushels produced last year and the 1939-48 average of 1,031 million bushels. The current crop overcame many obstacles in amazing fashion this season to attain the "billion bushel crop" distinction. Important among factors depressing production prospects earlier in the season were: (1) a 16 percent reduction in the over-all planted acreage from 1949 (2) excessive abandonment of winter wheat acreage in the Southern Great Plains States due to extended drought and green-bug infestations, and (3) extremely late planting of durum and other spring wheats in the important North Central producing area. However, moderate temperatures prevailed generally throughout July and August and favored development of the crop over the northern half of the country. As a result, the bulk of the grain produced was of excellent quality and high test weights while yields attained were generally above earlier expectations in most States. Above normal rainfall in June and July, although coming too late to materially benefit wheat in the Southwestern Plains area, was an important factor contributing to higher average yields, than appeared in prospect earlier in the season. Late planted spring wheats in North Dakota and Minnesota were favored by lack of extremely hot summer temperatures and an unusually late, pleasant fall, which permitted a slow, extended maturing process and the completion of harvest operations in October. The 1950 yield of all wheat is 16.6 bushels per acre, compared with 14.9 bushels for the 1949 crop and the 10-year average of 17.0 bushels.

The total acreage of all wheat harvested in 1950 was 61,741,000 acres, compared with 76,559,000 in 1949 and the average of 60,236,000 acres. The harvested acreage this year is 19.4 percent smaller than last year but 2.5 percent larger than average. The total acreage planted to wheat in the fall of 1949 and the spring of 1950 was 71,396,000 acres, compared with the record plantings of 84,662,000 acres for the 1949 crop. Abandonment due to adverse weather conditions, insects, and diseases, and diversion of some acreage to hay, pasture, and other uses amounted to 13.5 percent of the total planted acreage, compared with 9.6 percent last year.

WINTER WHEAT: The winter wheat cropis estimated at 750,666,000 bushels, 16 percent smaller than the 1949 crop of 895,101,000 bushels and the smallest production since 1943. A reduction of 15 percent in seeded acreage together with greater than average abandonment, contributed in large measure to the smaller crop this year. Of the 52,887,000 acres seeded, 17.2 percent was abandoned or not harvested for grain, leaving 43,816,000 acres for harvest, a reduction of 21 percent from the 55,129,000 acres harvested in 1949. The yield per acre this year, 17.1 bushels, is above the relatively low yield of 16.2 bushels last year, but slightly below the 10-year average of 17.5 bushels.

The wheat acreage allotment program was the main factor in the general reduction in winter wheat acreage seeded in the fall of 1949. Practically all States shared in the reduction, with Oklahoma, Texas and Kansas accounting for about 60 percent of the decrease. The crop for the most part was seeded under favorable conditions. Seeding was delayed by dry soils in some western States and by excessive moisture in parts of the Corn Belt, but most of the areas that were dry at seeding time received sufficient rains to bring the crop to a stand. Conditions were favorable for starting the crop in Nebraska, Kansas and most of Oklahoma and Texas.

CROP REPORT

as.of

December 1950

CROP REPORTING BOARD

Washington, D. C., December 18, 1950 3:00 P.M. (E.S.T.)

Loss of acreage during the winter and spring for the country as a whole was greater than usual, due largely to extreme drought and severe insect infestations in the southern Great Plains area. Low temperatures, in the absence of snow cover, and floods, caused above average losses in some North Central States. Extended winter and spring drought and severe infestations of green bugs resulted in nearly complete destruction of wheat in New Mexico and the important High Plains area of Texas. Losses from these causes were also unually heavy in southeastern Colorado, southwestern Kansas and much of Oklahoma. Only about one-fourth of the seeded acreage in New Mexico survived, and this too produced only low yields, losses in most of the Texas High Plains area were equally severe. Abandonment was not so heavy in other Texas areas, but for the State as a whole about 53 percent of the seeded acreage was lost. Abandonment was estimated at 28 percent for Colorado, 19 percent for Oklahoma and 11 percent for Mansas. Nebraska, with more timely rains and less insect infestation than other Great Plains States, had only a nominal abandonment of about 5 percent, Conditions were generally favorable in the Pacific Morthwest, where losses and diversions of seeded wheat acreage to uses other than for grain were much less than usual.

Timely rains and moderate temperatures in late spring and early summer resulted in some improvement over earlier prospects, especially in the Pacific Northwest and other late maturing areas. Per acre yields were near average or better in most States, but these were more than offset by exceptionally low yields in the southern Great Plains area.

ALL SPRING WHEAT: Production of all spring wheat is estimated at 276,089,000 bushels, up roughly 60 million bushels from earlier forecasts. The increased production was due to improved yields from late seeded acreage following very favorable weather in most spring wheat areas during late September and October. The current crop is 12 percent—roughly 30 million bushels—above last year's production of 246,087,000 bushels and is slightly above the 1939—43 average of 272,491,000 bushels. Harvested acreage of all spring wheat this season was 17,925,000 acres, down 16 percent from the 21,430,000 acres harvested last year, but up 3 percent from the 10—year average. Average yield per acre was 15.4 bushels compared with 11.5 bushels in 1949 and 15.7 for the 10—year average. Although spring seeding this year was generally two to three weeks, or more, later than usual, moisture conditions were satisfactory and cool temperatures favored the development of the crop in most of the principal spring wheat producing States.

Production of durum wheat is estimated at 36,064,000 bushels, 7 DURUM THEAT: percent less than last year's crop of 38,817,000 bushels and 2 percent below the 10-year average production of 36,753,000 bushels. Production was less than last year in Minnesota, and North Dokota. The acreage harvested, 2,729,000 acres, was 23 percent smaller than in 1949 but 8 percent larger than the average of 2,535,000 acres. The yield, at 13,2 bushels per acre, is sharply higher than the 11.0 bushels obtained last year but still below the 10-year average of 14.8 bushels. Yieldswere higher than last year in Worth and South Dakota but lower in Minnesota. The quality of the crop is quite variable with a wide range in test weights. Black stem rust was a serious threat in a large part of the durum area and some damage resulted. However, based upon final yield returns, the extent of damage from this cause was somewhat less than appeared imminent in the main durum growing counties just prior to actual harvest operations. Rust damage occurred largely on late seeded acreage in some fringe areas. Harvesting started considerably later than usual and extended through October in northern areas. Factors contributing to this were the unusually late planting, the generally slow growth

CROP REPORT as of

Washington, D. C., December 18, 1950 3:00 P.M. (2.S.T.)

CROP REPORTING BOARD December 1950

and development of the crop as a result of the cool summer temperatures, a rainy spell during harvest and the effects of stem rust in some areas which retarded

The seeded acreage of durum wheat is estimated at 2,814,000 acres, down 24 percent from last year and the smallest since 1946. North Dakota produced nearly 87 percent of the Nation's durum crop this year.

OTHER SPRING WHEAT: Production of other spring wheat is estimated at 240,025,000 bushels, an increase of 16 percent over last year's production of 207,270,000 bushels, and 2 percent above the 1939-48 average production of 235,738,000 bushels. The current estimate is up about 4 million bushels from the October forecast due chiefly to favorable weather conditions in October that brought fields seeded in June to maturity and generally enabled farmers to wind up harvest operations prior to the arrival of wet or freezing fall weather. Spring seeding which is usually completed by mid-May in the northern tier of States from Minnesota, westward, did not start in many counties until mid-May and continued until mid-June. Practically all of this late-seeded acreage was harvested during October and produced yields higher than anticipated earlier. Yield per acre was 15.8 bushels compared with 11.6 bushels in 1949 and the 10-year average yield of 15.9 bushels. Test weights this season were average or better, but protein content for most States was slightly below average. In Montana, subfreezing temperatures in late September and early October caught a sizeable acreage of spring wheat prior to maturity and resulted in considerable damage to the quality of this crop.

OATS: The 1950 crop is estimated at 1,465 million bushels, the fourth largest of record, exceeded only by the crops of 1945, 1946, and 1948. Production this year is 10 percent larger than in 1949 and 15 percent above the 1939-48 average. More than half of this production is from four States-Iowa, Minnesota, Illinois, and Wisconsin.

The crop was harvested from 42,027,000 acres, about 4 percent more than in 1949 and 8 percent above average. This year's seeded acreage amounted to 46,642,000 acres, 9.9 percent of which was diverted to uses other than grain or abandoned, compared with 8.9 percent in 1949. The seeded acreage this year was about 5 percent larger than the 44,387,000 acres seeded in 1949 and 9 percent above average. Large acreage increases in most West North Central, South Central, and Western States more than offset decreases in other areas, resulting in an increase for the country as a whole. Much of this increase can be attributed to the diversion of corn and wheat acreage to oats, as a result of the acreage allotment programs.

Cold, wet weather delayed spring seeding, particularly in northern and western States. The late season prevented some acreage from being seeded and as a result seedings in 1950 were below e rly intentions. Growing conditions prior to July 1 were less favorable than a year ago, particularly in Ohio, Indiana, Illinois, Michigan, and Minnesota. However, as the season progressed, cool weather and plentiful rainfall permitted the crop to make rapid progress and as a result the grain filled well. In most North Central States, where the crop was generally late, weather conditions were favorable for harvesting operations which were completed without serious losses. However, in Michigan wet weather caused some lodging and delayed harvest. Green bug damage was extensive in Oklahoma and Texas and caused considerable loss of acreage in that area.

The average yield per harvested acre was 34.9 bushels. This compares with the 1949 yield of 32.9 and the average of 32.8 bushels. Yields averaged higher than last year in all areas of the country with the exception of the South Central area. Green bug damage and dry weather caused low yields in Oklahoma and Texas. In the important North Central States, yields per acre were higher or the same as a year ago in all States except Indiana and Illinois.

CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C., December 18, 1950 3:00 P.H. (I.S.T.)

December 1950

3:00 Pails (I.S.I.)

BARLEY: Production of barley is estimated at 301,009,000 bushels, 27 percent larger than in 1949 and only 3 percent below the 10-year average production of 310,568,000 bushels, which includes the war years of high production. Production was larger than in 1949 in most of the important barley States, particularly California, North Dakota, and Minnesota. The yield per acre this year of 26.9 bushels was the second highest of records dating back to 1866; it was exceeded only by the record yield of 28.4 bushels obtained in 1915. Last year's yield was 24.0 bushels per acre and the average is 24.2 bushels. In the major-producing States the crop developed with a minimum of hazards and yields were generally above early season expectations. In California, excellent yields were obtained, especially on irrigated lands. In North Dakota, the crop developed slowly with excellent quality, and yields were the highest since 1942. High yields and excellent quality also were obtained in Minnesota. In Montana, yields were good despite mid-August frosts which caused some damage. In Colorado, the combination of heavy acreage abandonment due to winter killing of fall-planted barley, and sharply lover yields resulted in a crop only 41 percent as large as last year.

The acreage harvested this year was 11,191,000 acres, an increase of nearly 14 percent from last year but still 13 percent below the average of 12,858,000 acres. Acreage increases occurred in all of the North Central States except Nichigan and Mebraska. In the important producing States of North Dakota and Minnesota acreage increases over 1949 were 27 and 18 percent, respectively. In the Western group of States the acreage was 12 percent larger than last year with the largest percentage of increases reported in Montana and Washington. In California, the leading barley State, the acreage was up 11 percent. For the country as a whole, 15,4 percent of the planted acreage was abandoned or diverted to uses other than for grain compared with 11.9 percent in 1949.

Approximately 56 percent of the \overline{N} ation's barley crop was produced in the 4 States of California, North Dakota, Minnesota, and Montana.

The production of rye in 1950 totaled 22,977,000 bushels, 23 percent larger than the 1943 crop of 18,739,000 bushels, but 29 percent smaller than the 10-year average production of 32,155,000 bushels. Four States—Minnesota, North Dakota, South Dakota, and Nebraska—accounted for over half of the total 1950 production of rye. South Dakota, with a 5,250,000 bushel crop which was more than double its 1949 production, ranks first this year. Last year, South Dakota was third in production of this crop, being outranked by North Dakota and Minnesota. The yield per harvested acre this year is 12.6 bushels, compared with a yield of 12.0 bushels per acre for both last year and the 10-year average.

In the Southwestern plains area, yields were relatively low this season because of the extended drought during the early spring months. However, to the north in the more important grain producing States, rye yields were generally above average as soil moisture and prevailing temperatures were more favorable for the crop. Harvesting operations in central areas made rapid progress during July and by the first of August had advanced northward into the southern portions of North Dakota and Minnesota.

The acreage seeded to rye in the fall of 1949 and spring of 1950 for all types of utilization during the 1950 season, is estimated at 3,720,000 acres. This compares with 5,311,000 acres seeded a year earlier and the 10-year average of 4,997,000 acres. Harvested acreage for grain this year was 1,822,000 acres or 49.0 percent of the acreage seeded for the 1949 crop. Diversion of rye acre ge for uses other than

CROP REPORT as of December 1950

CROP REPORTING BOARD

Washington, D. C., December 18, 1950 3:00 P.M. (E.S.T.) ALTO DESCRIPTION OF THE PROPERTY OF THE PROPER

for grain was about normal. A sizeable acreage is usually diverted to other uses such as pasture, hay, vegetative cover, nurse or green manure crops. Last year, 1,560,000 acres, or 47.1 percent of the total seeded acreage, were harvested for grain. Over the 10-year period, an average of 52.9 percent of the total seeded acreage has been harvested for grain.

The production of buckwheat is estimated at 4,749,000 bushels, the lowest of record. The crop this year is nearly 9 percent below the previous record low production of 5,203,000 bushels in 1949 and about 32 percent below the 10-year average.

The acreage harvested this year, 266,000 acres, is also the smallest on record and compares with 280,000 acres harvested in 1949 and the 10-year average of 414,000 acres. The yield of 17.9 bushels per acre is a little below the 1949 yield of 18.6 bushels but above the 17.0 bushel 10-year average yield. Abandonment of planted acreage this year was considerably above last year and the average. crop was planted late and early frosts in the Northern States caught some of the crop before maturity. Wet weather hindered early harvest in some States, but dry weather in October favored the harvest of the later crop. Favorable weather conditions prevailed during most of the growing periods

Production of rough rice is estimated at 37,971,000 equivalent 100-pound bagso This is only 7 percent smaller than the 1949 record harvest of 40,747,000 bags but 27 percent larger than the 10-year average of 29,790,000 bags. Most of the acreage was planted at the optimum time under favorable conditions and experienced to good growing season without any storm damage or intrusion of salt water. The crop matured uniformily and was harvested under favorable conditions somewhat earlier than usual. Since a record yield per acre was obtained, this. year's smaller production was attributed to less acreage harvested which was primarily due to the reestablishment of acreage allotments.

The estimated 1,620,000 acres of rice seeded was 13 percent less than the 1,866,000 acres seeded in 1949 but 12 percent more than the 10-year average of 1,451,000 acres seeded. Abandonment of seeded acreage of 0.7 percent was less than last year and less than average. Due to the favorable weather very little acreage was abandoned in the southern area. In California, acreage abandonment was heavier than last year or average due to heavy rains near the end of the harvest season. The 1,608,000 acres harvested for the U. S. was about 13 percent less than the 1,840,000 acres harvosted in 1949 but 13 percent above the average of 1,428,000 acres harvested. A record yield of 2,361 pounds per acre was harvested this year, reflecting favorable growing and harvesting conditions, and compares with the 1949 yield of 2,215 pounds and the average of 2,094 pounds.

Rice production in the southern area, which includes Arkansas, Louisiana, Texas, and Mississippi, totaled 30,199,000 equivalent 100-pound bags compared with 50,513,000 bags in 1949 and the logger average of 23,779,000 bags. In Arkansas, about 14 percent less acreage was hervested than a year ago, but the yield of 2,325 pounds per acre was 100 pounds higher. The crop experienced a favorable growing season, and fair, dry weather in October and November enabled growers to combine their crops with a minimum of harvest loss. In Louisiana, the acreage harvested was 9 percent less than in 1949 but the yield of 1,925 pounds per acre was 125 rounds higher than in 1949. The season was favorable for the growth and maturity of rice and losses from all causes were a minimum. In Texas, a record production

CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C., December 18, 1950

December 1950 3:00 Р. 1. (E.S. I.) of good quality rice was harvested. Although about 10 percent less acrease was harvested than a year ago, the very high yield of 2,400 pounds per acre topped the 1949 yield by 400 pounds. The crop was harvested under almost ideal conditions with

no interference from tropical storms.

For Hississippi, estimates of rice acreage and production are published for the first time. The rice acreage in this State is concentrated in the Delta area near Greenville, Mississippi. About 5,000 acres were harvested in 1949 and 7,000 acres in 1950 from which the comparatively high yield of 2,700 pounds per acre was obtained.

In California, the estimated 232,000 acres harvested this year was about 23 percent less than the acreage harvested last year. The crop generally experienced a favorable growing season and a large proportion of the acreage was harvested under favorable conditions. However, heavy rains and continued wet weather in Hovember caused some loss of the unharvested acreage. The estimated yield of 3,350 pounds per acre this year is only 50 pounds below the 3,400 pounds obtained last year.

ALL SORG U.S (Including Sirup): The production of sorghum grain soared to a new record. The 1950 production of 237.5 million bushels is 28 percent above the previous record of 185 million bushels in 1944. Production this year was 56 percent larger than in 1949 and more than double the 10-year average. The sharp, increase in production may be attributed to the record acreage harvested for grain, as the 1950 yield per acre of 22.9 bushels compares with the 23.1 bushels per acre harvested last year. Sorghum growers utilized 10,361,000 acres for grain compared with 6,612,000 acres last year and the average of 6,552,000 acres. Below average yields in Colorado, North and South Dakota, Iowa, and Illinois were more than offset by above average yields in the central and southern Great Plains States. The 1950 grain crop got off to a relatively slow start during the early growing season as wet, cool weather at planting time prevailed over some of the more important grain producing areas. As the season progressed, conditions for growth and development were generally quite favorable. Even though the crop was later than usual this year, frost damage was light because the first killing frosts occurred relatively late in the main producing areas. The quality of sorthum grain was generally good, although some storage problems resulted from high moisture content at time of harvest.

Sorglum forage production of 7,360,000 tons compares with 6,541,000 tons harvested in 1949. The average yield of 1.55 tons per acre was below last year's average of 1.57 tons, but the harvested acreage was 14 percent above 1949. The 5,415,000 tons of sorghum silage compares with 4,414,000 tons of silage produced in 1949, both the acreage utilized for silage and the yield per acre were above last wear.

The total of 16.6 million acres planted to all sorghums in 1950 is 41 percent above the 11.8 million acres planted in 1949. Acreage increases of 35, 43, and 51 percent respectively, in Kansas, Oklahoma, and Texas accounted for 88 percent of the acreage increase in 1950. This increase may be largely attributed to the planting of sorghum on land removed from the production of wheat and cotton due to acreage allotment programs. The heavy abandonment of small grains in western and southern areas of Kansas and the High and Low Plains areas of Texas with subsequent seeding to sorghums was also a factor in the increased acreage in these States. The total sorghum acreage abandoned was relatively small and delayed frost permitted the bulk of the crop to reach maturity undamaged.

CROP REPORT

Washington, D. C., as of CROP REPORTING BOARD December 18, 1950

December 1950

3:00 P.M. (E.S.T.)

combine varieties are well adapted.

The trend continued toward greater utilization of sorghum for grain as 65.0 percent of the total harvested acreage was utilized for grain this year compared with 57.6 percent last year. This trend is the result of improved grain varieties and the large acreage increase in the central and southern plains areas, where

POPCORN: Popcorn growers in 11 commercial producing States harvested in 1950 approximately 249 million pounds of popcorn in the ear. This is 53 percent above the 159 million pounds harvested in 1949 and 26 percent above the 10-year average production of 192 million pounds. The relatively high production this year is due both to larger acreages harvested and larger yields per acre in most producing States. Acreage allotments on field corn, the relatively small popcorn production in 1949, together with a good demand late last year, were factors which contributed to acreage increases this year. Production is larger this year than last in all States where estimates are made except Michigan.

Iowa, with a crop of more than 50 million pounds, loads all other States in the production of popcorn this year. Indiana, second largest producer this year, harvested nearly 36 million pounds, compared with about 30 million pounds last year. Illinois, close behind Indiana, harvested about 35 million pounds compared with 32 million pounds last year. Missouri also harvested an unusually large crop because of increases in both acreage and yield per acre. In Kentucky, both acreage and yield per acre were above last year. Oklahoma almost doubled its 1949 acreage and production. No estimate is made for California because the acreage there has dropped to only a few hundred acres -- mostly for non-commercial use.

Growers planted 143,300 acres of popcorn this year, or 42 percent more than the 100,800 acres planted last year. Acreage losses in 1950 were relatively light. estimated 141,300 acres were harvested, or 43 percent more than the 98,700 acres harvested last year, and about 10 percent more than the 10-year average of 129,060 acres. The yield per acre this year was 1,720 pounds of ear corn, compared with 1,614 pounds last year and the average of 1,482 pounds. Yields were larger than last year in most areas except in the eastern Corn Belt States. The larger United States yield per acre this year than last is due primarily to better yields in most of the States where acreage increases were large. Although conditions at planting time were unfavorable in many areas, the long growing season enabled most late popcorn to mature.

In Gallatin County, Illinois, less than half the crop had been planted by June 1, but because of the long frost-free fall most of this corn matured so that the quality is good to very good. About 87 percent of the acreage in Illinois was planted with hybrids, Purdue 31, 32, and 38 accounting for 79 percent of the acreage compared with 71 percent last year. In Ohio, about 90 percent of the acreage was planted with hybrid varieties, mostly of the Purdue strains. Weather in Kentucky during October and early Movember was nearly ideal for curing and picking popcorn and about 90 percent of the 1950 crop in that State had moved from farms by December 1. Texas also produced a crop of good quality this year. Fairly important quantities of popcorn were produced in several other States for which no official estimates are made.

The hay crop harvested this year totals nearly 107 million tons. It is the third largest crop in the eighty-five years of record, being exceeded slightly in 1942, and again in 1945 when more than 108 million tons were made. The 1949 crop

CROP REPORT

CROP REPORTING BOARD

Washington, D. C., December 18, 1950

December 1950 3:00 P.M. (E.S.T.)

was only a little more than 99 million tons. The 1950 crop, plus the carryover of 15 million tons of old hay, provides more hay per animal unit to be fed than in any other year for which comparable data are available.

Production of hay in 1950 nearly equals or exceeds that of last year in most of the important northern, southwestern, and far western States, except Maine, Missour Texas, Colorado, Wyoming and Utah. In the southerstern States this year's hay crop is generally a little less than in 1949 and in some of them is less than average, but in this region need for hay in recent years has been partly offset by prolonged use of better pasturage.

The 73 3/4 million acres of crops cut for hay this year has been exceeded in several other years, but is $1\frac{1}{4}$ million more than average and 2 3/4 million more than in 1949. More than 1 million of the increase in acreage over last year is in Illinois and Iowa and another million is in the States of Minnesota, North Dakota. South Dakota and Montana,

Although the average 1950 yield of all hay of 1.41 tons per acro is but little less than the highest (1.44 tons) in forty years, the per acre yields in 20 States are less than in 1949. Some of these are in the Southeast where hay is a minor crop, but in others-such as Illinois, Missouri, Arkansas, Oklahoma, Colorado, Wyoming, Utah, Idaho and Nevada-hay is a highly important item in crop production. On the other hand, 1950 hay yields per acre in the three Pacific Coast States, in most of the North Central States and in the northeastern dairy States — all very important producers of hay — are well above those of the previous year. In many of the northern and northeastern States weather in 1950 was better for growing than for harvesting, so considerable rain damaged and overripe hay was harvested.

More than one-fourth of the entire 1950 hay crop is clover-timothy. About 30 million tons of this kind were cut from some 21 million acres, mostly in the northern and western States. This is by no means a record crop, but it totals nearly 5 million tons and 2 million acres more than the relatively small crop harvested in 1949.

The 1950 alfalfa hay crop of 41 million tons made from 18 million acres establishes a new record for both production and acreage, being 2 million tons and 1 million acres larger than the previous record crop made in 1949. In most of the important States the acreage cut for hay in 1950 is a little larger than in the previous year. The largest acreage increases are in Minnesota, Wisconsin and adjacent States. Minor increases or decreases are reported from States farther west where there has been some trouble with we wil. Moderate reductions occurred in some Mississippi Valley States.

The lespedeza hay crop in 1950 is a million tons less than in 1949. Only 72 million tons were made from about 62 million acres. Late spring frosts damaged the young crop in some States. In others, dry, fall weather restricted yields of this kind of hay. Since lespedeza is harvested later than most other kinds of hay some was not cut because farmers already had as much hay as they wanted.

The 1950 wild hay crop is $12\frac{1}{2}$ million 'ons, which is about $\frac{1}{4}$ million tons more than harvested in 1949 and about half a million tons more than the 10-year average. Cold weat er in the spring retarged the growth in the Morth Central area. We

CROP REPORT as of

Washington, D. C., Becember 18, 1950 1950 3:00 P.M. (E.S.T.)

December 1950

CROP REPORTING BOARD

ample moisture supplies caused rapid growth during the summer months. Some of the early cut hay was rain damaged. Yields per acre equaled or exceeded 1949 yields in the 5 leading States - North Takota, South Dakota, Nebraska, Minnesota and Montana. For the U. S., both acreage and yield per acre are slightly above last year.

FLAXSMED: Production of flaxseed this year is estimated at 39,263,000 bushels, 11 percent below the 43,946,000 bushels produced in 1949 but 13 percent above the average of 34,752,000 bushels. North Dakota with a production of 16,102,000 bushels replaced Minnesota as the leading flaxseed State in the Nation during 1950. Minnesota was second, with a production of 13,255,000 bushels, followed by South Dakota with 4,527,000 bushels. About 86 percent of the 1950 total U. S. flaxseed crop was produced in these three States.

This year's crop was harvested from 3,893,000 acres, 21 percent below the 4,924,000 acres harvested in 1949 but still 7 percent above the 1939-48 average of 3,643,000 acres. Morth Dakota, with 1,695,000 acres harvested, was down only 6 percent from a year ago while Minnesota with 1,205,000 acres harvested and South Dakota with 503,000 acres were down 26 to 29 percent, respectively. The 1950 seeding season was generally very late in the major flax States. The comparatively small decrease in North Pakota can be attributed to some extent to some seeding of flax when it was too late to seed other spring crops. The total seeded acrege in the United States in 1950 was 4,064,000 acres, compared with 5,226,000 acres seeded a year earlier.

Abandonment was 4.2 percent of the acreage seeded and compares with 5.8 percent in 1949. Wet weather during harvest time was the principal cause for heavy acreage abandonment in Kansas and Oklahoma, while in Arizona some early flax was frozen out, In Montana, North Dakota, and South Dakota, abandonment was less than a year ago but was slightly larger in Minnesota.

The 1950 yield of 10.1 bushels per acre was well above the 8.9 bushels a year ago and the 1939-48 average of 9.5 bushels. Final yield returns were better than expected earlier in the season. Adverse weather conditions delayed seeding, and some acreage near the Canadian border was seeded as late as early July. There was some question about the late-seeded acreage maturing, but most of the crop was harvested and losses were relatively light.

FIAX FIBER: Oregon grovers produced 1,480 tons of flax fiber straw this year on the 800 acres harvested for fiber production. In 1949 a total of 4,140 tons were harvested on 2,300 acres. The reduction in acreage this year was due primarily to unfavorable spring weather and to comparatively poor returns for flax fiber in relation to other crops.

COTTON: A cotton crop of 9,884,000 bales of 500 pounds gross weight is estimated for 1950, based on information as of December 1. This is the eighth crop of less: than 10 million bales since the turn of the century. The small crop this year was due to the reinstatement of acreage allotments, failure of farmers to plant their full allotted acreages, and below-average yields per acre in central and eastern Cotton Belt States. The 1949 crop of 16,128,000 bales was the largest since 1937 and the fourth largest on record. Eroduction in 1948 was 14,877,000 bales and the 1939-48 average 11,599,000 bales.

CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C., December 18, 1950 December 1950 3:00 P.M. (E.S.T.)

The acreage of cotton in cultivation on July 1 was 18,654,000 acres which compares with 27,719,000 acres in 1949 and 21,859,000 for the 10-year average. Gross abandonment since July 1 of this year (abandonment from natural causes and acreage removed from cultivation to comply with acreage allotments) is indicated at 4.3 percent, leaving 17,850,000 acres for harvest. With the exception of 1945 and 1946 when 17,083,000 and 17,674,000 acres, respectively, were harvested, this year's harvested acreage is the smallest since 1884. As a result of severe weevil damage and unfavorable weather, abandonment attributed to natural causes was heavier than average.

The 1950 lint yield per acre, computed at 265.4 pounds, is 4.1 pounds above the 10-year average and compares with the 1949 average of 284 pounds. Record yields per acre in California and Arizona of 770 and 771 pounds, respectively, are indicated this year. These average yields of around one and one-half bales per acre are about three times the average for the United States. In Florida, New Mexico, Louisiana, and Texas, yields were also above average. In Texas, below-average yields were made in central and eastern counties. However, these low yields were more than offset by above average yields in irrigated northwestern Texas areas. In all other States the yields were moderately to sharply below average.

Boll weevil infestation in 1949 was relatively high and the number of weevils entering hibernation in late fall of that year was considerably above average. winter of 1949-50 was the mildest of record and the number of boll weevils emerging in the spring of 1950 was at a high level in all areas and at record levels in eastern cotton States. Intensive and widespread poisoning was begun earlier than ever. During July frequent rains and below average temperatures, especially during the latter half of the month, hindered the application of poisons in most States. In some areas the supply of insecticides was inadequate.

In weevil infested States showery weather continued in most areas through August and September, while below average temperatures prevailed. The maturity of the crop was delayed and heavy weevil damage continued. Damage to practically manure bolls was excessive in many areas. However, conditions were favorable in Est Mexico, Arizona, and California, and the cotton crop made satisfactory progress during August and September.

October weather was exceptionally favorable for harvesting the crop throughout the Belt. With open weather and above average temperatures prevailing, bolls opened rapidly and harvesting operations proceeded satisfactorily. Temperatures were again below normal in November but good progress in harvesting the crop continued in most States. By December 1 practically all cotton was harvested in North Carolina, South Carolina, Georgia, Alabama, Mississippi, and Louisiana. In Texas, Oklahoma, New Mexico, and Arizona the percentage of the crop to be harvested after December 1 is less than at this time last year. In mid-November floods in some areas of California interfered with picking for a few days; otherwise harvesting operations progressed satisfactorily. In Arkansas, Tennessee, and Missouri, the percentage of the crop harvested to December 1 was less than at that time last year, as a result of late crops and some unfavorable weather. For the United States, about 90 percent of the crop was ginned by December 1 compared with 87.9 percent for 1949 and the 10-year average of 89.6 percent.

The Bureau of the Census reports 8,790,417 running bales were ginned from the crop of 1950 prior to December 1, compared with 13,975,840 hales for 1949 and 12,744,152 bales for 1948.

UNITED STATES DEPARTMENT OF AGRICULTURE

BUREAU OF AGRICULTURAL ECONOMICS

CROP REPORT
as of
December 1950

CROP REPORTING BOARD

Washington, D. C., December 18, 1950 3:00 P.M. (D.S.T.)

American Egyptian cotton was not under acreage allotments this year. The acreage of this cotton in cultivation on July 1 is indicated at 103,500 acres, compared with 5,600 acres last year. Production on the 100,700 acres for harvest is estimated at 58,300 bales, compared with 4,000 bales in 1949 and the 10-year average of 27,800 bales. Practically all of the American Egyptian acreage is in Texas, New Mexico, and Arizona.

If the ratio of lint to cottonseed is the same as the 1945-49 average, production of cottonseed this year would be 4,005,000 tons, compared with 6,559,000 tons in 1949 and the 10-year average of 4,730,000 tons.

HENP hemp fiber mills did not contract any acreage in Wisconsin for the 1950 scason, and no acreage of record is being grown in any State. In 1949, 4,700 acres of hemp were planted and 4,500 acres harvested with production indicated at 4,950,000 pounds. In recent years Wisconsin has been the only State producing hemp for fiber.

The Nation's crop of hempseed is produced entirely in Kentucky, primarily to plant the Wisconsin hemp fiber acreage. With no fiber acreage in Wisconsin this year, most of the hempseed produced on the 200 acres harvested for seed in Kentucky last year is still available. In view of this, no acreage was grown for seed this year. In 1948 a total of 400 acres were harvested for seed.

SOYBEANS: Soybean production in 1950 reached an all-time high. The crop this year is estimated at 287 million bushels—56 million bushels above the previous record crop of 1949. Soybean production has increased tremendously during the last 10 years with the crop this year 3½ times as large as in 1940. Production did not reach 100 million bushels until 1941, and the first 200 million bushel crop was not reached until 1946. The 1939-48 average production is 164.5 million bushels. This year's bumper crop came as a result of a large acreage harvested for beans and a relatively high yield of 21.6 bushels per acre. The yield this year, however, is well below the record of 22.7 bushels harvested in 1949. The 10-year avorage yield is only 18.8 bushels per acre.

A total of 15.4 million acres of soybeans were planted for all purposes in 1950, about 25 percent more than in 1949. This is a near record, being exceeded only by 20 thousand acres in 1943. The 13.3 million acres actually harvested for beans is a record and is about one-third larger than in 1949. The increase in acreage this year came largely from land diverted from crops under acreage allotments, especially corn, cotton, and in limited areas wheat and peanuts. Also, as soybeans can be planted later than most spring planted crops, they were used to take the place of oats and other crops which could not be planted because of poor weather in some areas. The relatively high price of soybeans this spring was also an incentive to increase plantings.

The 1950 growing and harvesting season for soybeans was very unusual. Planting was delayed in some localities because of cold, wet weather but in general the crop was planted under favorable conditions. The growing season in the principal soybean areas was favorable in that moisture was abundant, but cooler than average weather prevailed during the entire season. This delayed maturity and harvesting started rather late. The weather then turned warmer than seasonal allowing late planted soybeans to mature without loss. Harvesting progressed under the most favorable conditions. Practically the entire crop was combined by December 1, with only minor losses.

- 19 -

CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C., December 18, 1950

December 1950 3:00 P.M, (E.S.T.)

The heavy producing North Central States harvested more than 250 million bushels of soybeans this year or about 42 million bushels more than in 1949. Illinois alone had a crop of 95 million bushels, although the yield of 24 bushels per acre was two bushels less than the record set last year. Froduction was well above last year in all the North Central States but yields per acre in most States ran lower. The exceptions were Missouri, Mebraska, and Kansas, where record yields were obtained. The South Atlantic States had a good season with yields averaging higher than in 1949 but acreage increases there were not large. Production for the arca was near 10 million bushels, about 2 million bushels more than in 1949. The South Central States showed the highest percentage increase in production from a year ago. The area contributed 26 million bushels to the United States production compared to only 14 million last year. Arkansas, with nearly 12 million bushels this year, had more than doubled last year's outturn. Mississippi had nearly 7 million bushels in 1950, compared with less than 2 million last year. These increases came as a result of sharply increased acreage and from exceptionally high yields on the Delta land, much of which was diverted from cotton in 1950.

COWPEAS: The acreage of cowpeas planted for all purposes in 1950 is estimated at 1,479,000 acres, a decrease of about 12 percent from last year. This is only 44 percent of the 10-year average and is the lowest acreage in the 27 years of record. The production of cowpeas for dry peas is indicated at slightly under 5 million bushels compared with just over 3 million bushels last year. This is the lowest production of record also and is only about 60 percent of the 10-year average. Production has declined in most years since 1941 when a record 8 million bushels were harvested.

The season was favorable for cowpeas and the indicated yield of 6.5 bushels per acre is 0.3 bushel above last year and 1 bushel above the 10-year average. Texas, the heaviest producing State, reported yields above average but below a year The total production in that State, however, is above 1949 due to the increased acreage harvested. The other major producing States, South Carolina, Alabama, and Mississippi, also reported above average yields this year.

A higher percentage of the total acreage planted for all purposes was used for peas and for purposes other than hay this year than in 1949 or the 10-year average. The percentage for hay has declined sharply-only 24 percent of the total was harvested for hay in 1950 compared to an average of 34 percent. L'bout 31 percent was harvested for peas compared with an average of 28 percent. Other purposes, largely soil improvement, accounted for the remaining 45 percent in 1950 while the average is only 38 percent.

The 1950 production of peanuts for picking and threshing is estimated at 2,038 million pounds compared with 1,876 million harvested in 1949. Final outturn of the current crop is larger than was expected earlier in the season and is only 13 percent below the record crop of 2,338 million pounds harvested in 1948. Weather conditions were very favorable during the harvesting season in most areas and the crop was saved in excellent condition and with a minimum loss. I total of 2,315,000 acres was harvested for picking and threshing this year compared with 2,332,000 acres in 1949. The 1950 yield per acre of 881 pounds is the largest of record and is 20 pounds above the previous high yield of 861 pounds in 1940.

In the Virginia-Carolina Area, cool nights and excessive rainfall during the spring months delayed the peanut crop and prevented proper cultivation. Late in the season weather conditions were favorable and the largest yields per acre of

CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C., December 18, 1950: December 1950 3:00 P.M. (E.S.T.)

record were harvested in Virginia. Production for this area is placed at 473 million pounds compared with 443 million harvested in 1949. Acreage for picking and threshing is estimated at 389,000 or an increase of 3 percent from the 379,000 acres harvested last year.

In the Southeastern Area, weather conditions were generally favorable and record yields per acre were harvested in Georgia, Florida and Alabama. yield per acre of 909 pounds in this area is 125 pounds above the previous record of 784 pounds produced in 1940. Production is placed at 1,107 million pounds or 14 percent above the 973 million pounds harvested a year ago. The acreage picked and threshed in this area is estimated at 1,218,000 acres, compared with 1,252,000 acres in 1949.

The crop in the Southwestern Area turned out better than was expected earlier in the season. Production here is estimated at 458 million pounds compared with 460 million last year. Dry weather reduced yields from the early crop in South Texas, but the weather improved and better yields then expected were harvested in North Texas and also in Oklahoma.

VELVETBEANS: Velvetbeans staged a comeback this year. The 1950 production is estimated at 413,000 tons, about 23 percent above last year and the highest production since 1946. The crop reached its peak in 1940 when nearly a million tons were produced. Since that time there has been a rather steady decline in both acreage and production. This year's increase is due primarily to heavier plantings as a result of the smaller peanut and cotton acreage. The crop is grown only in the deep South and is usually interplanted with corn, being used almost entirely as a forage crop or for soil improvement. Very few velvetbeans, except those needed for seed, are actually harvested.

The 1950 plantings are estimated at 934,000 acres, an increase of 20 percent over last year but about 43 percent below average. More than 60 percent of the acreage is in Georgia with Florida and Alabama ranking next in importance. Small acreages are also grown in South Carolina, Mississippi and Louisiana. The 1950 season was generally favorable with yields averaging above both last year and the 10-year average.

The 1950 dry edible bean crop of 15,128,000 bags (100 pounds cleaned basis) is about 24 percent below the 1949 crop of 19,890,000 bags, and 6 percent smaller than the 10-year average production of 16,110,000 bags.

By classes, the production of Pintos now leads all others with a crop of 3,638,000 bags (100 pounds clean basis) compared with a 1949 crop of 3,966,000 bags. Pea beans are in second place with production estimated at 3,241,000 bags, compared to 5,304,000 bags last year. Michigan produced almost 93 percent of the pea beans this season. Great Horthern bean production is estimated at 1,838,000 bags, a sharp decrease from the 1949 crop of 3,168,000 bags. Standard Limas in California are estimated at 1,225,000 bags, 11 percent less than last year's production of 1,376,000 bags, while production of Baby Limas is 1,132,000 bags, a decrease of about the same percentage below the 1949 crop of 1,272,000 bags.

Reductions in acreage are indicated for all of the major bean producing States, primarily due to acreage allotments for most kinds. For all States the acreage reduction amounts to 19 percent. Michigan had a heavy loss of acreage from excessive rains, while dry weather in several other States also reduced acreage

UNITED STATES DEPARTMENT OF AGRICULTURE BUREAU OF AGRICULTURAL ECONOMICS

CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C., December 18, 1950

December 1950 3:00 P.M. (E.S.J.)

harvested. Abandonment of planted acreage amounted to 8.5 percent compared with only 2.5 percent last year. Generally, however, weather conditions were fairly favorable for the development of the crop. The average yield per acre of 1,128 pounds is the second highest yield on record, and is exceeded only by last year's yield of 1,163 pounds. Larger yields than last year were obtained in Nebraska, Montana, Idaho, Washington, and California, while Maine, New York, Michigan, Wyoning, Colorado, New Herico, and Utah all reported lower yields per acre. Arizona's yield was the same as in 1949.

In New York, production is estimated at 1,261,000 bags compared with 1,540,000 bags in 1949. Planting of the crop was timely and development quite favorable. In July a rather severe infestation of the Mexican bean beetle was controlled by an intensive program of dusting, after limited damage. Prolonged damp weather in September, when the white bean crop was being pulled, caused heavy discoloration and a "pick" of from 30 to 40 percent in some fields.

In Michigan, a sharp decrease of 19 percent in the harvested acreage occurred, and the yield was down from 1,100 pounds in 1949 to 950 this year. Production is estimated at 3,312,000 bags compared with 5,502,000 bags in 1949. The crop was planted a little earlier than usual, and the favorable weather which followed resulted in rapid development of the crop. However, beginning in late July frequent rains, continuing on to the end of the season, drowned out many whole fields and caused such severe damage to others that growers did not consider them worth harvesting.

Idaho produced 2,239,000 bags of beans this year which is about 5 percent less than the 1949 crop of 2,347,000 bags. Due to the continued shift toward the growing of higher yielding Pintos the average yield of 1,850 pounds is at a record level in spite of somewhat unfavorable weather.

In Colorado, an 8 percent loss of the planted acreage resulted from rather unfavorable growing weather in the southwest and eastern dryland areas. Yield ber acre averaged 760 pounds, 100 pounds below the 1949 yield but approximately 1.10 pounds above the 10-year average.

In California, yields per acre were good and above the 10-year average, as well as above the 1949 average by a small margin. Late October rains caused heavy damage to beans still unharvested at that time, and some rather severe losses occurred.

DRY PEAS: The Hation's 1950 crop of dry peas is estimated at 2,979,000 bags of 100 pounds each, uncleaned, which is equivalent to 2,731,000 bags of cleaned peas. Production this year is the smallest since 1940, being 9 percent below last year and 49 percent below the 10-year average production. On a cleaned basis, this year's production of smooth green, white, and yellow varieties, chiefly utilized as food, is 2,041,000 bags, 12 percent below the 1949 crop. Production of other dry peas, mostly wrinkled varieties used for seed, totaled 690,000 bags, a 7 percent increase over 1949. Washington produced 68 percent and Idaho 23 percent of the varieties chiefly utilized as food, while Idaho led all States in the production of wrinkled peas for seed.

Planted acreage of all dry peas in 1950 was 240,000 acres--down 34 percent from the 1949 planted acreage, and the smallest since 1939. The harvested acreage of dry peas was 219,000 acres compared with 334,000 in 1949, and the 10-year average of 454,000 acres.

- 22 -

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 18, 1950

December 1950

3:00 P.M. (E.S.T.) An average yield of 1,360 pounds of dry peas (uncleaned) was produced this year compared with 975 pounds in 1949 and the 10-year average of 1,246 pounds. Generally favorable soil and weather conditions prevailed during the growing season in the Palouse district, which extends from eastern Washington into northwestern Idaho. The harvesting period in this major district was two weeks later than usual and combines were able to finish harvesting only just before arrival of fall rains.

The Oklahoma 1950 mung bean crop is estimated at 12,250,000 pounds compared with 8,000,000 pounds in 1949. The largest production during the nine year history of mung beans in Oklahoma was 24,200,000 pounds in 1945. Mung bean production became important during World War II when shipments from China were stopped. Since 1945, the production in Oklahoma has fluctuated between 8 million and 15 million pounds annually. The 1950 crop was the best yielding crop since 1942; the average yield was 350 pounds per acre compared with 320 pounds in 1949 and the 1944-48 average of 230 pounds. Moisture conditions in the early summer were ideal for planting and germination and fall weather was ideal for harvesting.

Oklahoma harvested 35,000 acres of mung beans compared with 25,000 acres in 1949. Approximately 45,000 acres were planted this year compared with 35,000 acres last year. About one-half of the 1950 crop is estimated to have moved into commercial channels. The remainder will be used mostly for seed and feed. Demand was fairly good for the 1950 crop until the needs of sprouters were satisfied. Small quantities of mung beans are grown in other States, but estimates are prepared only for Oklahoma.

SUGAR BEETS: The largest sugar beet crop ever produced in the United States was harvested this year. Production of beets from the 1950 crop is estimated at 13,383,000 tons. This compares with 10,197,000 tons produced in 1949 and the 10-year average production of 9,938,000 tons. This year's large crop results from a near record acreage and above average yields per acre.

Dry, cold weather at and immediately after planting hindered early development of the crop in most areas. Later weather generally was unusually good for growth and development of the crop; irrigation water supplies were ample and the crop had an exceptionally good growing season except for some hail damage in Nebraska. Excellent weather continued through harvest in all areas except Wyoming, where snowfall and low temperatures delayed digging. Freeze damage there was small, however, for the snow provided ample protective covering for the beets. The expanded acreage resulted in a long campaign for sugar companies, especially in California.

On the basis of operations through mid-November, sugar companies report an expected production of 1,871,000 tons of beet sugar, refined basis, compared with 1,462,000 tons last year and the previous record crop of 1,756,000 tons in 1940.

SUGARCANE SIRUP: Production of sugarcane sirup in 1950 is estimated at 10,830,000 gallons, the smallest crop of record. This compares with 11,920,000 gallons produced in 1949, the previous record low, and the 10-year average production of 20,042,000 gallons.

All States except Louisiana had a smaller crop this year than last. In that State yields per acre are above 1949.

UNITED STATES DEPARTMENT OF AGRICULTURE BUREAU OF AGRICULTURAL ECONOMICS

CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C. December 18, 1950 December 1950 3:00 P.M. (E.S.T)

SUGARCANE FOR SUGAR: Sugarcane from the 1950 continental crop to be used for sugar making is now estimated at 6,620,000 tons -- 5,382,000 tons in Louisiana and 1,238,000 tons in Florida. The volume of cane used for sugar from the 1949 crop totaled 4,994,000 tons in Louisiana and 1,127,000 tons in Florida. Sugar production from cane ground from the 1950 crop is expected to be 457,000 tons in Louisiana and 105,000 tons in Florida, totaling 562,000 tons, raw value. Production last year was 520,000 tons, made up of 416,000 tons from Louisiana and 104,000 tons from Florida.

Insufficient rainfall in late August and September lowered early season prospects in Louisiana, but the dry weather proved very favorable during harvest. About half the crop in this State received some degree of freeze damage. This damage can vary considerably depending on further weather developments. Grinding operations are at full capacity to avoid or reduce loss of frozen cane that would result from souring after thawing No serious damage has been reported to the Florida crop from hurricanes or cold weather.

SORGO SIRUP: Production of sorgo sirup in 1950 is estimated at 6,383,000 gallons, the second smallest crop of record and compares with the record low 1949 crop of 6,012,000 gallons.

The increase in this year's production over last year was the result of increased acreage in most major producing States. The national acreage for 1950 is estimated at 101,000 acres, or 12 percent larger than the record small 1949 acreage of 90,000 acres.

MIPLE PRODUCTS: Production of maple products in 1950 was somewhat higher than in either of the past 2 years even though operations extended over a shorter period. Trees tapped in 1950 are estimated at 7,711,000 compared with 7,924,000 in 1949. A total of 1,968,000 gallons of sirup was produced, compared with 1,614,000 gallons in the previous year. Sugar production, following the long time trend, is down to 262,000 pounds from 292,000 in 1949. Prior to 1936 the production of this item had never been below 1,000,000 pounds and was above 11,000,000 pounds in 1918.

The 1950 season was the most satisfactory in several years for the larger producing States, The season was characterized by an abundance of moisture, about the normal amount of frost in the ground and cool temperatures late in the season. This was conducive to good runs of sap particularly in the Northern sections of the belt.

TOBACCO: A total production of 2,036 million pounds of tobacco is estimated for 1950. This is about 3 percent above last year's crop when 1,972 million pounds were grown. This increase in production over 1949 was brought about in spite of lower acreages in 1950. The acreage harvested this year is 1,594,000 acres compared with 1,631,000 in 1949. The average yield in 1950, at 1,277 pounds per acre, is slightly above the previous record established in 1948 when 1,274 pounds were harvested.

The United States crop of flue-cured tobacco for 1950 is placed at 1,256 million pounds, about 13 percent above last year's production. This is the third largest of record, having been exceeded in 1946 and 1947 when 1,352 million and

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONOMICS

Washington, D. C., f CROP REPORTING BOARD Tecember 18, 1950 3:00 P.M. (E.S.T.)

December 1950

1,317 million pounds, respectively, were harvested. The acreage this year was up only 2 percent from 1949. The average yield 1,316 pounds per acre, is a new high and compares with last year's yield of 1,191 pounds and the previous record high of 1,233 pounds per acre in 1948.

The early season start for flue-cured tobacco was more or less typical, Tifficulties of getting plants, local problems with blue mold, excessive rains and irregular stands were common. Timely rains, favorable growing conditions, good cultivation and adequate fertilization all contributed to overcoming the early handicaps in most areas. The yield per acre of flue-cured tobacco was the highest record.

The production of fire-cured tobacco, at 57.7 million pounds, is about 14 million below last year, and establishes a new low record for the series (since 1919). The acreage, at 53,100 acres, is also the lowest of record and compares with 60,400 acres harvested in 1949. The season was characterized in Kentucky and Tennessee by persistent and excessive rainfall throughout the early and middle parts of the growing season. Wildfire losses were severe in some fields.

The <u>burley</u> crop is estimated at 499 million pounds, and compares with 560 million pounds in 1949. This reduction is accounted for by lower acreages and yields than last year. The 1950 harvested acreage is 405,300 acres, compared with 453,400 acres in 1949. Excessive moisture before planting time and throughout most of the growing season resulted in excessive growth of stalks. In many fields in middle and western Tennessee and Kentucky maturity was delayed and rotting of the lower banes caused considerable damage. Relatively good weather at harvest time reduced the hazard of house-burn which was reported in some sections.

Production of dark air-cured is placed at 30.6 million pounds - down more than 5 million pounds from last year. Weather conditions were comparable with fire-cure tobacco, and the yield per acre is down somewhat from 1949. Most of the reduction, however, was brought about by lower the acreage which is 29,000 acres, compared with 32,100 acres harvested last year.

The production of cigar tobaccos is estimated at 152 million pounds, slightly more than the 148 million pounds harvested in 1949. The estimated production of fillers, 71.9 million pounds, compares with last year's production of 69.1 million pounds. Binders are placed at 66.5 million pounds, 7 percent above last year, whil wrappers at 14.0 million pounds are down about 18 percent from 1949.

BROOMCORN: Production of bropmcorn brush, estimated at 25,900 tons, is the smallest of record. Also, this tonnage is 42 percent smaller than the 44,800 tons harvested in 1949 and 37 percent smaller than the 10-year average of 41,170 tons. Production in each of the six important broomcorn producing States was considerably smaller than in 1949, and average, principally due to smaller plantings and unfavorable weather during the growing season.

For these States, plantings of 215,500 acreas were 18 percent smaller than the 262,000 acres planted last year and 27 percent smaller than average plantings of 294,800 acres. About 29,000 acres, or 13.5 percent of these plantings were not harvested because of drought, diseases, floods, poor quality brush, and other causes. Abandonment of planted acreage was greater than last year, and average, in Oklahoma, Colorado and New Mexico; slightly greater than last year but less than average in Texas; and practically none in Illinois and Kansas, The crop was

UNITED STATES DEPARTMENT OF AGRICULTURE BUREAU OF AGRICULTURAL ECONOMICS

CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C., December 18, 1950 December 1950 3:00 P.M. (E.S.T.)

harvested from an estimated 186,500 acres, or about one-fourth less than the 247,000 acres harvested in 1949 and 29 percent smaller than the 10-year average of 263,400 acres harvested. The acreage harvested was considerably less than last year, and average, in Oklahoma, Colorado and New Mexico; less than last year but slightly above average in Texas; and slightly less than last year but about twothirds less than average in Illinois and Kansas.

The estimated yield of 279 pounds per acre compares with 362 pounds in 1949 and the average of 311 pounds. Lower yields than a year ago were reported for each of the six States with the greatest decline in yields occurring in Texas, Colorado and New Mexico,

The 1950 bacomcorn season was quite variable within States as well as between States and areas. In Illinois, the crop was planted in good time and made favorable progress during most of the growing season. However, late season rains interfered with harvesting and caused considerable low quality brush. In Kansas, dry weather early in the season retarded plant development. Late season rains also caused some development of root rot which together with some insect damage was injurious to the final outturn of the crop. The crop in the Lindsay area of Oklahoma made reasonably favorable early season growth, but sucessive heavy rains during the harvest season lowered quality and caused some loss of brush. In the Panhandle area of Oklahoma the crop was late, but delayed frosts enabled most of the acreage to produce some brush. In south Texas, yields were generally low because of dry weather, but the quality of the brush was good, while in central and northern sections of Texas a reasonably good crop of broomcorn was produced, In Colorado and New Mexico much replanting was necessary because of extended early season drought. Growth was slow and irregular, thereby delaying harvest. Yields were low and quality was fair to poor.

HAY SEEDS: The 1950 production of the six major seed crops-alfalfa, red clover, alsike clover, sweetclover, lespedeza, and timothy -- totals approximately 609.6 million pounds of thresher-run seed. This is 10 percent larger than the 1949 production and 27 percent larger than the 1939-48 average. Carry-over of these seeds in the aggregate is 42 percent larger than in 1949, but 3 percent smaller than the 10-year average. Current supplies (production plus carry-over) of the six seeds are about 13 percent larger than last year and 18 percent larger than the average.

A record crop of red clover/crop of alfalfa seed, the largest sweetclover seed crop in 11 years, and the largest timothy seed crop in 7 years were produced in 1950. However, below average crops of alsike clover seed and lespedeza seed were produced. Production of four of these seeds -- sweetclover, alsike clover, red clover, and timothy turned out 3 to 19 percent larger than was forecast, whereas production of two--lespedeza and alfalfa--was less than I percent smaller than was forecast.

Harvesting of these seeds, except alfalfa, began later than usual in 1950 and average 6 or 7 days later than in 1949. Movement of each of the six seeds from farms was slower in 1950 than in 1949, and also slower than usual except for alsike clover. Loss in cleaning the 1950 crop of each of these seeds, except

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORT as of

follows:

CROF REPORTING BOARD

Washington, D. C., December 18, 1950 3:00 P.M. (E.S.T.)

December 1950 3:00 P.M. (E.S.T. alsike clover, is expected to be larger than for the 1949 crop, and in each case the loss is above average. However, the quality of the 1950 crops of these seeds averages fairly good, three kinds being of better quality and the three others of somewhat poorer quality than in 1949. Additional information regarding these seeds

Alfalfa Seed: The 1950 production of alfalfa seed is estimated at 1,878,700 bushels of thresher-run seed. This is 6 percent smaller than the record 1949 crop of 1,996,700 bushels, but 44 percent larger than the 10-year average of 1,303,960 bushels. Production in the southern group of States is nearly 3 1/2 times the average, whereas production in the central group is 20 percent below average, and in the northern group only 7 percent above average. Production by regions is as Collows: Northern, 618,700 bushels in 1950, 803,700 bushels in 1949, and the average of 576,150 bushels; Contral, 381,000 in 1950, 664,000 in 1949, and the average of 475,930; Southern, 879,000 in 1950, 529,000 in 1949, and the average of 251,880.

An estimated 884,100 acres of alfalfa were harvested for seed in 1950. Nearly one-tenth of this acreage represented improved varieties that were entered for certification and that are adapted for sowing in northern and contral regions. In 1949, a total of 1,005,500 acres of alfalfa seed was harvested, compared with the average of 881,640 acres. The 1950 yield of 2.12 bushels per acre is 7 percent larger than the 1.99 bushels in 1949 and 43 percent above the average of 1.48 bushels.

Red-Clover Soed: As forecast 2 1/2 months ago, the 1950 production of red-clover seed is the largest on record. It is estimated at 2,638,300 bushels, thresher-run nearly 500,000 bushels more than the previous record crop of 2,141,800 bushels in 1946, twice as large as the 1949 orop of 1,319,200 bushels, and 60 percent larger than the average of 1,645,290 bushels. Larger crops were produced in 1950 than in 1949 in 15 out of 18 producing States, with increases largest in Indiana, Illinois, Ohio, and Iowa.

Approximately 2,537,000 acres of red-clover seed were harvested in 1950. This is more than twice the 1,235,000 acres in 1949 and nearly half again as many acres as the average of 1,766,990. High prices received by growers for this seed during the last three years, record hay supplies in relation to the number of roughageconsuming animal units to be fed and unusually good pastures; and favorable weather and insect conditions influenced growers to harvest for seed in 1950 the second largest acreage ever harvested. The 1950 yield per acre of 1.04 bushels is almost equal to last year's yield of 1.07 bishels--largest in 8 years-and nearly 0.1 bushel above the average of .95 bushel.

Alsike-Clover Seed: The 18 percent increase in the 1950 production of alsike clover seed over that of 1949 is more than offset by the much smaller carryover currently than a year ago. This year's crop is estimated at 315,400 bushels, compared with the 1949 crop of 266,600 bushels and the average of 340,370 bushels. The larger production this year in Minnesota and Ohio accounted for most of the difference between the total 1949 and 1950 production.

An estimated 110,300 acres of alsike clover scod were harvested in 1950 compared with 107,500 acros in 1949 and the average of 134,660 acros. The 1950 yield of 2.86 bushels per acre is exceeded only by the 2.92 bushels in 1947 and is due chiefly to the very large yields in Oregon and California, where over a third of the 1950 crop was produced.

BUREAU OF AGRICULTURAL ECONOMICS

CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C., December 18, 1950 December 1950

Sweetclover Seed: With crops in 13 out of 15 States larger this year than last, and also larger than average, the 1950 production of sweetclover seed is the largest in 11 years. It is estimated at 1,403,600 bushels, or 49 percent larger than tho 1949 production of 943,300 bushels and 87 percent larger than the average of 751,600 bushels.

Tho 447,500 acres harvested for seed in 1950, third largest on record, compare with 311,600 acres in 1949 and the average of 282,600 acres. The record high prices received by growers for their 1949 crop seed were chiefly responsible for the large acreage harvested in 1950. Because of favorable weather and the greatly increased acreage in Texas, where yields were high, the United States yield of 3.14 bushels is the largest in 13 years. It compares with 3.03 bushels in 1949 and the average of 2,66 bushelse

Lespedeza Seed: The 1950 production of lespedeza seed is the third smallest in 10 years, but it is offset in part by the largest carry-over on record. This year's production of 163,120,000 pounds thresher-run is 34 percent smaller than the large 1949 crop of 248,300,000 pounds and 8 percent below the average of 178,191,000 pounds. The 1950 crops in 13 out of 16 States were smaller than those of 1949.

Chiefly because prices of 1949 crop lespedeza seed were the lowest in 7 years and the carry=over was at a record level, growers harvested only 740,600 acres of this seed -second smallest acreage in 10 years. It compares with 1,005,000 acres in 1949 and the average of 846,940 acres. The 1950 yield of 220 pounds per acre is 27 pounds less than in 1949, but 12 pounds more than the average.

Timothy Seed: With acreage and yield in each of the 8 producing States larger than in 1949, the 1950 production of timothy seed is more than twice the small 1949 crop and 21 percent above the 1939-48 average. It is estimated at 1,607,000 bushels, largest production in 7 years, and compares with 793,400 bushels in 1949 and the 10-year average of 1,328,520 bushels. Carry-over of old timothyseed is the smallest on record.

The record high prices received by growers for timothy seed in 1949 and a plentiful supply of hay influenced growers this year to harvest 460,800 acres, largest in 11 years, 66 percent larger than the 278,300 acres harvested in 1949 and 23 percent above the average of 375,110 acres. The 1950 yield of 3.49 bushels is more than a fifth larger than the 1949 yield of 2.85 bushels, but slightly below the average of 3.53 bushels.

HOPS: The 1950 crop totaled 58,336,000 pounds -- 15 percent above 1949 and 27 percent above average. Salable allotments under the 1949 and 1950 marketing agreements total 39 million pounds for 1949 and 50 million pounds for 1950. Almost 5 million pounds of unsalable hops under the marketing agreement were harvested last year but only about 1 1/2 million pounds were harvested from the 1950 crop. About 800,000 pounds of the 1950 unsalable hops have been destroyed by fire.

Production estimates by States compared with last year are as follows: Washington, 24,081,000 pounds -- up 24 percent, Oregon, 16,279,000 pounds -- up 11 percent, California, 16,121,000 pounds -- up 5 percent, and Idaho, 1,855,000 pounds -- up 33 percent. Acreage for the 4 States totaled 38,800 acres -- 3 percent more than in 1949. The 1950 acreage and yield were higher than 1949 in each State.

CROP REPORT

BUREAU OF AGRICULTURAL ECONOMICS

Washington, D. C.,

as of CROP REPORTING BOARD December 18, 1950
December 1950
3:00 P.M. (E.S.T.) CONTERCIAL APPLES: Commercial apple production in 1950 was 120,499,000 bushels. 10 percent below the 1949 crop but 10 percent above the 10-year avera e of 109,408,000 bushels. Only 2.0 percent of the 1950 crop or 2.4 million bushels were not harvested or dumped after harvest because of low prices and other economic conditions. In 1949 there were 11.9 million bushels of economic abandonement. Acove average crops were produced in all areas except in the Central States. Compared with the 1949 crop, the larger production in the South Atlantic States offset the small crop in the North Atlantic States. A smaller crop was produced in the Central States than a year earlier, while in the Western States the increase this year for Washington partly offset the declines in the other Western States. The 1950 production by varieties shows about the same size crop of Delicious, McIntosh and Winesap as a year ago. A smaller percentage of this year's crop was of summer and fall varieties. Delicious is the largest producing variety with a production of 27 million bushels this year, followed by Winesap and McIntosh with 13 million each. The good crop of York Imperial at 7.5 million is the fourth ranking variety. The Rome crop with 7.2 million is fifth, while Jonathan with a production of 6,3 millions is sixth. The largest changes from a year ago by varietics are Jonathan, down 32 percent, York Imperial, up 62 percent, and Gravenstein, down 46 percent,

The eastern crop totaled 56.0 million bushels this year, or slightly under the 56,4 million produced in 1949, but about 9 million above average, Five States, Mew York, Virginia, Pennsylvania, West Virginia and Massathusetts, produced fourfifths of the total crop in the region. Production in the Shenandoah Valley and Piedmont area was up sharply from the relatively poor crop of 1949, but in most other areas, especially in New York and Pennsylvania, the 1950 crop fell somewhat below the previous year's outturn. The Delicious crop was smaller than a year ago in the Eastern States. The 3,718,000 bushels produced this year compares with 4,409,000 in 1949. About one third of the eastern Delicious was produced in Virginia. The McIntosh variety this year showed a production of 11,529,000 in the Eastern States (about 88 percent of the national total) and was down slightly from the 12,064,000 million produced in these States in 1949. The production of Stayman in the Eastern States was 3,874,000 bushels - slightly less than the 3,950,000 bushels produced in 1949. The smaller crop of Stayman in the North Atlantic States was practically offset by larger crops in the South Atlantic States, A larger crop of Winesam in Virginia resulted in a good tonnage of this variety in the East, The Virginias had a good set of York Imperial; the 7,289,000 bushels produced in the Eastern States this year compares with 4,382,000 bushels in 1949.

In the Central States, the commercial apple production is estimated at 17.9 million bushels compared with 23,4 million bushels in 1949 and the 10 year average of 19,4 million. The Michigan crop was slightly above average but for most areas, in the other Central States production was down considerably from a year ago and was also below average. The Grines Golden crop in the Central States at 1,032,000 bushels was down about a third from a year ago, while the Jonathan crop, at 2,707 000 bushels, was about one half of the large 1949 production and 15 percent below average. The Rome Beauty crop was down 24 percent from a year ago, Stayman was down 21 percent, Winesap down 28 percent, Delicious down 28 percent, Golden Delicious down 39 percent, McIntosh down 32 percent and Northern Spy 3/1 percent,

The Western States had a crop of 46.5 million bushels. This compares with 49.0 million in 1949 and the average production of 43.2 million, All States in this group except Washington had smaller crops than a year ago and also smaller

CROP REPORT

BUREAU OF AGRICULTURAL ECONOMICS

Washington, D. C., December 18, 1950

as of

CROP REPORTING BOARD

December 1950 3:00 P.II. (I.S.T.)

than average. Washington production was 34,592,000 bushels-up 9 percent from 1949 and 25 percent above average. A heavy set of fruit followed a later-than average blossoming period, in Washington. The crop developed under ideal weather conditions. but harvesting was delayed 2-4 weeks and picking was not completed until the first week of November, California production of Gravenstein was 1,559,000 bushels, or a little more than half the 1949 crop. The Jonathan crop in the Western States was 3.1 million, down about 5 percent from last year, The larger crop of Rome Deauty in Washington this year did not offset the smaller crops in the other Western States. The production this year was 2.6 million in this area, down 13 percent from 1949. The Winesap crop in Washington this year was 10,032,000 bushels, up about one-half million from a year ago. Washington produced about 77 percent of the Mation's total of this variety. The crop of Delicious in Washington this year, 19,441,000 bushels, made up over two-thirds of the Nation's production of this variety, In 1949, Washington produced 18,042,000 bushels of Delicious. The production of Yellow Newton this year in the Pacific States was 3,925,000 bushels, down 15 percent from a year ago,

The quantities of apples unharvested because of economic conditions this year with the 1949 figures in parentheses, by regions are as follows: (in bishels) North Atlantic States 1,114,000 (3,967,000); South Atlantic States 221,000 (none); Central States 214,000 (4,845,000); and Western States 806,000 (3,089,000).

PEACHES: Production in 1950 totaled 52,573,000 bushels, 30 percent below the 1949 crop of 74,818,000 bushels, 20 percent below the short 1948 crop of 65,352,000 and 25 percent below average. Production this year was shortest in the southern States, Washington, Oregon, Utah, Idaho and Colorado, where spring freezes or low winter temperatures killed the fruit buds. The crop in the Fortheast was about average, while Michigan, Chic and Missouri had above average crops. The other important Central States showed a production below last year and average.

In the 10 southern neach States (N.C., S.C., Ga., Fla., Alae, Miss., Ark., La., Okla. and Texas) the 1950 production was 6,103,000 bushels or less than half the 1949 production of 12,940,000 bushels and only about one third of average. The freezing weather in late March and April following the above average temperatures during the late winter months killed or damaged the crop severely in these States. The Morth Carolina crop was 548,000 bushels or about 38 percent of the 1949 crop of 1,428,000 bushels. South Carolina's crop was 468,000 bushels this year compared with 2,340,000 bushels in 1949. Georgia had 975,000 bushels this year compared with 2,040,000 bushels in 1949. Texas had a crop of only 783,000 bushels in 1950-33 percent of the 1949 crop. Arkansas had a fair crop with a production this year of 1.980,000 bushels, 82 percent of the 1949 crop.

The crop in New York and New England suffered damage from freezing in late February and early March. The crop in the Middle Atlantic States (N.J., Pa., Va., W. Va., Del. and Ild.) was also damaged by late freezes. The production in these States in 1950 was 6,186,000 bushels, 21 percent less than the 1949 crop of 7,844,000 bushels but 3 percent above the 1948 crop of 6,031,000 bushels, Michigan had a good crop with a production of 4,080,000 bushels-17 percent above a year ago.

In Washington, the low winter temperatures severely reduced the crop and killed many trees. Production was only 135,000 bushels, 5 percent of the 1949 crop. This is the lowest production since 1909. Peaches in Oregon totaled 299,000 brishels or about 31 percent of the 1949 crop of 979,000 bushels. The crop in the

CROP REPORT as of

BUREAU OF AGRICULTURAL ECONÓMICS

Washington, D. C., December 18, 1950

CPOP REPORTING BOARD Pecember 1950 3:00 P.M. (D.S.T.)

Hood River, the Dalles and Milton-Freewater area was almost a failure but a fair crop was produced in southern Oregon. The Utah crop this year was 130,000 bushels or 17 percent of the 778,000 bushels harvested in 1949. Colorado had about 58 percent as large a crop this year as in 1949.

In California, peach production totaled 29,460,000 bushels, 5,751,000 bushels below the 1949 crop of 35,211,000 bushels, but 299,000 bushels above average. The crop this year was damaged by frosts in March. California clingstone crop was 19,663,000 bushels this year or 4,417,000 bushels below a year ago. California freestones were 9,792,000 bushels-1,334,000 bushels below 1949.

Peaches not utilized this year because of low prices, shortage of labor and other factors amounted to 100,000 bushels in Michigan and 1,250,000 bushels of cling neaches in California.

PEARS: The pear crop is estimated at 31,263,000 bushels-14 percent less than last year but slightly more than average. Production in the 3 Pacific Coast States totaled 25,783,000 bushels, which is 13 percent less than the 1949 production but 12 percent above average. Bartletts for these States are estimated at 18,969,000 pushels and other pears at 6,814,000 bushels. These groups are both less than last year but above average. Low temperatures last winter in Washington and Oregon damaged rany trees and reduced the Eartlett crop. The production of other pears in Washington was about one-tenth less than last year. Oregon produced a record crop of Anjous, which comprise more than two-thirds of the total fall and winter varieties. The crop of these varieties in Oregon is 6 percent above 1949. The New York crop at 1,055,000 bushels and the Michigan crop at 812,000 bushels are each above average but below last year.

The 1950 grape crop is estimated at 2,640,900 tons, slightly less than last year and 5 percent below average. The California crop is now estinated at 2,411,000 tons, compared with 2,485,000 produced last year. Wine varieties this year totaled 535,000 tons, table varieties 569,000 tons and raisin varieties 1,307,000 tons. Production of wine grapes was about the same as last year, table grapes were 11 percent more but raisin varieties 9 percent less. Production of lried raisins is estimated at only 150,000 tons compared with 262,000 tons last year and 256,100 tons average. Zante currents are included with raisins. No economic abandonment is expected for California this year.

The Great Lakes area (New York, Pennsylvania, Ohio, Michigan) had a large crop of 161,200 tons -- 43 percent above last year and 33 percent above average. Storages and processing plants were "hard-put" to handle the crop. Grapes unharvested because of low prices or difficulties in marketing the fruit are estimated at 3,400 tons - 2,200 tons in New York and 1,200 tons in Pennsylvania.

CITRUS: Total orange production for the 1950-51 season is forecast at 106.5. million boxes--3 percent above the 1949-50 crop and 11 percent above average. Early and midseason oranges are indicated at 51.6 million boxes-slightly more than last season. Valencias are indicated at 54.9 million boxes-5 percent more than last season. The grapefruit crop is forecast at 48.5 million boxes-33 percent more than the 1949-50 total but 4 percent less than average. The forecast for California lemons is 12.5 million boxes, 7 percent above last season.

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORT as of

CROP REPORTING BOARD De dember 1950

Washington, D. C., December 18, 1950 3:00 P.M. (E.S.T.)

Florida production of early and midseason oranges is indicated at 34 million boxes and Valencias at 27 million boxes-l percent and 8 percent, respectively, more than last season. Tangerines are forecast at 4.8 million boxes-4 percent less than last season. The grapefruit crop is expected to total 31 million boxes--28 percent more than last season. Texas oranges are forecast at 3.5 million boxestwice the short crop of last season and about the same as the 1948-49 crop. Grapefruit are indicated at 12 million boxes compared with 6.4 million last season and 11.3 million in 1948-49. Arizona weather was exceptionally warm during October and November, which hastened maturity of citrus fruits. Arizona grapefruit are estimated at 3 million boxes and oranges at 1 1 million. California Navel and Miscellaneous oranges are indicated at 14.5 million boxes -- 7 percent less than last season. The first forecast of the season for Valencias is for 25.9 million boxes --- 2 percent less than the 1949-50 crop. The Desert Valley's grapefruit forecast at 1.1 million boxes is a little above the 1949-50 crop, but summer grapefruit at 1.4 million boxes is a little below last season. Picking in the Desert Valleys had barely started by December 1 and most of the grapefruit in other areas will not be harvested until next summer. California lemons are forecast at 12.5 million boxes-7 percent above last season.

PLUMS AND PRUNES: Production of plums in California and Michigan this year totaled 82,900 tons. This is 13,200 tons less than the 1949 crop but is 12,400 tons larger than the 1948 crop and 2,320 tons above average. The high temperatures in early July caused some damage to the California crop. The 78,000 tons produced in California in 1950 were 12,000 tons less than last year. Michigan had a 4,900 ton-crop-about four-fifths of the 1949 crop.

The California prune crop of 147,000 tons was 5,000 tons below a year ago and 43,600 tons below average. High temperatures in early July, caused some loss by sunburn and heavier than normal shedding.

The Northwest crop (Idaho, Washington and Oregon) was extremely short. The production of 44,800 tons was 28 percent of the 1949 crop and 36 percent of average. In Idaho, eastern Washington and eastern Oregon, where the bulk of the production is shipped to fresh market, the crop totaled 26,300 tons or 44 percent of the 1949 production of 60,100 tons. For western Oregon and western Washington, where most of the crop usually goes for processing, low winter temperatures killed most of the fruit buds. The production in this area was 18,500 tons or 19 percent of the 1949 production of 99,000 tons and 27 percent of average.

The utilization of the crop in 1950 shows fresh sales of 25,600 tons, 147,500 tons dried, 12,000 tons canned, and 1,500 tons frozen. These compared with fresh sales of 51,020 tons from the 1949 crop, 161,200 tons dried, 26,550 canned, and 3,700 tons frozen.

CHERRIES: Production of sweet cherries in the most important producing States (N.Y., Pa., Ohio, Mich., Mont., Idaho, Colo., Utah, Wash., Oregon and calif.) in 1950 was 81,660 tons, 41 percent below the 1949 production of 137,700 tons and 5 percent below average. Low winter temperatures reduced the crop materially in the Northwest. Washington with 17,600 tons and Oregon with 17,400 tons had crops only about one-half as large as the 1949 production in these States. The California crop of 31,000 tons was 13,000 tons less than last year but 4,150 tons above average. In the other Western States, the crops were much less than last year and except for Montana were below average. The low temperatures reduced the crop in these States. In the East, record large crops of 7,400 tons and 4,300 tons were produced in Michigan and New York, respectively.

CROP REPORT

BUREAU OF AGRICULTURAL ECONOMICS

Washington, D. C.,

as of

CROP REPORTING BOARD

December 18, 1950

herries produced mainly in the discountry of the December 1950 Sour cherries, produced mainly in the Great Lakes area, were a record large production in 1950. The 160,350 tons produced this year were 42 percent above last year and 72 percent above average. Michigan with a production this year of 98,000 tons was 37,500 tons above 1949 and exceeded the 1948 crop, the previous record, by 29,000 tons. The New York production of 27,100 tons was 9,600 tons above last year and exceeded the previous record crop of 27,000 tons produced in 1942. The crop in Pennsylvania of 9,500 tons was 500 tons larger than the 1949 crop, the next highest of record. Conditions in Michigan, Ohio, Pennsylvania and New York were very favorable for the set and production of cherries this year, although in New York the high wind in Wayne Gounty on July 18 caused some damage to the crop. The Wisconsin crop exceeded the 1949 crop but was only 55 percent of the record large crop of 1948. The sour cherry crop in Montana, Idaho, Colorado, and Utah was below a year ago. The combined crop in Washington and Oregon was about the same as in 1949.

APRICOTS: Production for the 3 important States (California, Washington and Utah) was 202,100 tons, 2 percent above the 1949 production but 13 percent below average. California with 200,000 tons had a crop 21 percent above last year, while Washington and Utah with 1,700 and 400 tons, respectively, had a near failure The crop in these two States was only 6 percent of last year's production, and was utilized mostly for home consumption and roadside sales.

CRANBERRIES: Production in the 5 States (Massachusetts, New Jersey, Wisconsin, Washington and Oregon) this year is 980,300 barrels-139,900 barrels above last year and 265,720 barrels above average. The production in 1950 is the highest of record, exceeding the previous record crop in 1948 by 12,600 barrels. The production this year in Massachusetts exceeded the 1949 crop by 100,000 barrels New Jersey by 31,000 barrels, Wisconsin by 15,000 barrels, and Oregon by 900 barrels. Washington was the only State showing a smaller crop than in 1949, with a decline of 7,000 barrels.

In the Eastern States the season, though late, was generally favorable for the development of the crop. Harvest of cranberries in Massachusetts was generally completed by the first of November. The berries were of good size and quality and the culling from screening was less than usual. The crop in New Jersey was of good quality. In Wisconsin, the size of the berries was generally small and the waste in screening will be higher than usual. In the northwest, the fruit in Washington did not size as well as expected. The wet weather during October in Oregon delayed harvest and the low prices resulted in 2,100 barrels not being harvested. In Washington, 5,000 barrels were not harvested. The amount of excess cullage for all States is placed at 52,000 barrels: 34,000 barrels in Massachusett: 3,000 in New Jersey and 15,000 in Wisconsin.

AVOCADOS, FIGS, OLIVES, The production of avocados was 25,200 tons this year, 31 percent above 1949 and 39 percent above average. The DATES AND PINEAPPLES: fruit from the California crop is quite spotted. The production this year in California is 19,700 tons, compared with 14,300 tons in 1949 and the 10-year average of 15,400 tons. The Florida crop, at 5,500 tons, is 10 percent above the 1949 crop of 5,000 tons and more than twice the 10-year average of 2,703 tons.

In California this year the dried fig production was 23,800 tons and not dried totaled 11,000 tons. These totals compare with the dried production of 28,400 tons and a fresh crop of 8,000 tons last year. The Texas fig crop used for processing was 590 tons, or 70 tons less than a year ago. The production of figs this year was below average in both States.

CROP REPORT as of

December 1950

BUREAU OF AGRICULTURAL ECONOMICS CROP REPORTING BOARD

Washington, D. C., December 18, 1950 # The second sec

The 1950 production of olives in California was 43,000 tons. 8,000 tons above 1949 but 4,900 tons below average. The fall weather was favorable for the harvestin of olives for canning.

California date production in 1950 was 15,100 tons, 7 percent above a year ago and 57 nercent above average.

Florida pineapple production this year was 6,500 crates, 30 percent above the 5,000 crates produced in 1949 but 29 percent below average.

PECANS: Production in the 10 States (N.C., S.C., Ga., Fla., Ala., Miss., Ark., La., Okla., and Texas) this year was 112,503,000 pounds. This is 12 percent below the 1949 production and 7 percent below average. Georgia and Texas with crops of 35,750,000 and 35,000,000 pounds, respectively, account for 63 percent of the U.S. production. Georgia's crop this year is almost double the short crop of 18,000,000 harvested in 1948 but is about 10 percent below the 1948 crop of 39,600,000 pounds. Weather conditions in Georgia were favorable for carrying out an effective spray program and the crop is very clean. The Schley variety has the largest production of recent years. The Texas crop this year exceeds the 1949 crop by 6,000,000 pounds but is 22,000,000 pounds below the large crop produced in 1948. Oklahoma with, a crop of 6,000,000 bounds has the smallest production since 1942. The damage from insects and disease was unusually severe in this State. The crops in Alabama, Mississippi and Locisiana were small, being only 63 percent, 36 percent and 54 percent, respectively, of last year's production. Shedding was heavy in these States.

The production this year was 53,383,000 for improved varieties and 59,120,000 for wild or seedling necans. The crop in 1949 consisted of 47.373.000 pounds of improved varieties and 80,801,000 of seedlings.

ALMONDS, FILBERTS AND WALNUTS: Almond production in California this year is 36,600 tons-15 percent below the record crop of 1949 but 57 percent above the 10-year average production of 23,310 tons.

The combined walnut crops of California and Oregon are estimated at 64,000 tons-down 27 percent from the 1949 production and 3 percent below average. Heavy rains during late October in Oregon interfered with harvesting. The California crop turned out slightly better than expected as damage from high temperatures in midsummer and early fall was not as heavy as indicated earlier.

The filbert crop in the Pacific Northwest is estimated at 6,120 tons-45 percent below the record 1949 production of 11.140 tons but is slightly larger than average. Poor pollinating weather in Oregon and Washington caused a very uneven set of nuts-especially on DuChilly variety trees.

TUNG NUTS: The crop of 38,750 tons this year is the smallest since 1945. Spring frosts caused a light set of nuts in all States. The 1950 crop is 44 percent of the record high 1949 crop of 87,900 tons. Tung nuts, a relatively new crop in the United States, have shown a sharp increase in production since 1939. Production by States for 1950 is as follows: Mississippi, 18,000 tons; Louisiana, 10,300 tons; Florida, 9,000 tons; Alabama, 950 tons; and Georgia, 500 tons. Production in each of the States is only about half of last year.

UNITED STATES DEPARTMENT OF AGRICULTURE BUREAU OF AGRICULTURAL ECONOMICS

CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C., December 18, 1950 3:00 P.M. (E.S.T.) December 1950 3:00 P

The upward trend in potato yields continued during 1950 and, despite the lowest acreage since 1876, a crop of about 100 million bushels more than National requirements was produced. Estimated production of 439,500,000 bushels exceeds last year's crop by 7 percent and is 9 percent above average. year's crop has been exceeded only by the 1948, 1946 and 1943 productions. Growers planted 1,866,000 acres to potatoes, compared with 1949 plantings of 1,934,000 acres and the 1939-48 average of 2,718,000 acres. The estimated 1,847;000 acres harvested are 3 percent smaller than last year's acreage and slightly more than two-thirds of average. Even though prices to growers were disappointingly low at harvest, the acreage that was not dug because of low prices is insignificant.

Yields were excellent in practically all areas and the national average of 238

tushels exceeds the previous record high yield per acre by 22 bushels.

A reduction in the commercial acreage reflects some further cut in acreage allotments this year; acreage grown primarily for farm consumption also continued to decline. As growers reduce pote to acreage they utilize the land best adapted to this crop. They also further increased the rate of seeding and used more fertilizer this year. Commercial growers again followed intensive spray and dust programs. In addition to these practices, which are designed to produce high yields, the growing and harvesting seasons were very favorable in practically all producing areas. Temperatures during the growing season were generally slightly below normal and the moisture supply was adequate.

For the 29 late States, production is estimated at 342,986,000 bushels, compared with the 1949 crop of 323,772,000 bushels and the 1939-48 acreage of 312,497,000 bushels. The 1,314,000 acres harvested in these States are 4 percent smaller than last year's acreage and 32 percent below average.

For the 3 surplus late States in the East (Maine, New York and Pennsylvania), acreage was 12 percent below last year, but record-high yields were obtained in each State and production declined only 5 percent. Planting of the smaller acreage in Maine was completed shortly after the first of June and growing conditions were favorable. In northern Aroostook County, top growth was damaged by frost on September 12, and freezes during the September 22-25 period terminated growth in all parts of Maine. Some freezing of tubers, which is showing up in storage, occurred during the September 22-25 period. Except for this damage, quality of tubers is very good

On Long Island, all varieties yielded satisfactorily, but movement during the summer and fall was retarded as demand was weak. The Pennsylvania crop was planted a little later than usual, but the cool growing season with adequate moisture in most commercial areas favored growth and the crop developed rapidly.

Record high yields were harvested in each of the 5 surplus late States in the central part of the country-Michiga, Wisconsin, Minnesota, North Dakota, and South Dakota-despite a late spring in the Red River Valley and minor August frost damage in Wisconsin, Michigan, Minnesota, and western North Dakota. The 404,000 acres harvested in these States is 4 percent smaller than the 1949 acreage but only three-fifths the 1939-48 average. The Red River Valley crop was planted late, but moisture was abundant at planting time and continued adequate throughout the growing season. A late growing season enabled the crop to overcome the effects of late planting. August frosts in Wisconsin caused some concern but damage was light.

UNITED STATES DEPARTMENT OF AGRICULTURE BUREAU OF AGRICULTURAL ECONOMICS

CROP REPORT

Washington, D. C., as of CROP REPORTING BOARD December 18, 1950
December 1950
3:00 P.M. (E.S.T.

Acreage in the 10 surplus late States of the West was 2 percent above last year, with Idaho contributing most of this increase. The 436,000 acres harvested in the 10 States was 6 percent below average. Estimated production of 127,310,000 bushels exceeds the previous record high crop harvested in 1948 by 1 percent. A crop of 109,349,000 bushels was harvested in 1949 and the 1939-48 average is 102,401,000 bushels. In this group of States, record high yields were produced in Nebraska, Montana, Colorado, Utah, Nevada and California. Except in Idaho, acreage harvested was about in line with earlier estimates. In that State, potato acreage on new land brought into production this year was greater than previously estimated. Quality of Idaho tubers is good and sizes are smaller than in 1948 when the record high yield was attained and many over-sized tubers were dug. Both the early and late crop in Nebraska produced high yields. Irrigated yields in the late commercial areas of that State were particularly good. Freezing weather in October caused some damage to tubers in Montana, but the extent of such damage will not be known until potatoes are taken out of storage. In the San Luis Valley of Colorado, there was some hail damage in early August, but the extent of this damage was not as serious as growers first expected. Yields in northern Colorado were exceptionally high this year. Movement of the Utah crop has lagged as demand has remained weak. Compared with 1949, production is down slightly in the Malheur-Baker County area of Oregon, but a larger crop has been produced in central Oregon and the Klamath Basin. Conditions in the Klamath Basin were almost ideal and the highest yields of record have been harvested on both the Oregon and California acreage in this area. The late California acreage that was marketed in the summer and early fall produced yields about in line with recent years. In that State, the late acreage for winter harvest is expected to produce good yields as most vines remain green.

For the 11 other late States, the 136,000 acres harvested are 5 percent smaller than last year's acreage and only about one-half average. In the New England States of this group, conditions throughout the growing season were favorable for potato production. The phenomenal yields obtained by several large commercial growers tended to give a yield for Indiana that is considerably higher than previously estimated.

The 32,205,000 bushels estimated for the 8 intermediate States is about an average crop but 18 percent larger than last year's production. Most of this increased production is in New Jersey where dry weather seriously reduced yields last year, but the 1950 growing season was almost ideal. Government purchases were exceptionally large in New Jersey and the delay in digging permitted tubers to continue adding tonnage beyond the usual time of harvest.

An expanded acreage in California caused a slight increase in acreage for the early potato States. Production for these States is placed at 64,309,000 bushels, compared with last year's crop of 60,492,000 and the 1939-48 average of 58,275,000 bushels. Yields in California were reduced by frosts. During peak marketing of the California crop, many of the low grade potatoes were dumped. A record-high yield of commercial early potatoes was produced in North Carolina despite the fact that frosts killed back some plants as many as three times. These frosts delayed movement causing an overlap between marketings from North Carolina and Virginia. This overlap was the principal factor that forced the Government to be the principal purchaser of this crop. Under such conditions, digging was delayed and tubers added considerable tonnage after the usual time of harvest.

BUREAU OF AGRICULTURAL ECONOMICS

CROP REPORT as of

CROP REPORTING BOARD

Washington, D. C., December 18, 1950 December 1950 3:00 P.M. (E.S.T.)

SWEETPOTATOES: A record high yield and some increase in acreage combined to produce a sweetpotato crop that exceeds the production of each of the last three years. Estimated production of 58,729,000 bushels is 6 percent larger than last year's crop but 5 percent below average. Growers harvested 563,000 acres of sweetpotatoes, compared with 551,000 acres in 1949 and the 1939-48 average of 683,000 acres. The record high yield of 104 bushels harvested this year is 4 bushels higher than the 1949 yield and 13.6 bushels above average.

Acreage harvested is somewhat smaller than estimated in July. At that time, an acreage at least as large as was harvested in 1949 was indicated for each of the sweetpotato producing States except Kentucky and Oklahoma. However, fall surveys indicate acreage reductions from 1949 for Delaware, Indiana, Tennessee, Kentucky, Arkansas, Maryland, Alabama and Georgia ranging from 22 percent in Delaware and Indiana to 3 percent in Georgia. Acreage was expanded in North Carolina, Mississippi, New Jersey, Florida, South Carolina, Louisiana and California with the largest percentage increases in California and Louisiana, where much of the crop is grown commercially. There was also some expansion of commercial acreage in other local areas, particularly in the Carolinas, Georgia and Mississippi. Yields were generally good in all States.

Even though digging of the New Jersey crop was delayed, the heavy set yielded a larger-than-usual percent of small sized sweetpotatoes. The proportion of the crop going into storage is less than for any recent year as the lower grades were marketed when dug.

In the South Atlantic States, conditions generally favored development and harvest of this crop. In each of these States, above average yields were dug. Except in Georgia and Florida, where yield prospects were reduced by early season drought, yields exceeded those of 1949.

In each of the South Central States, yields were above average. Only in Tennessec, Arkansas and Texas are yields below those of 1949. A wet season in Tennessee caused excessive vine growth and "root" growth did not catch up with vegetative development. Texas yield prospects were reduced by dry weather in July and August. Production in Louisiana is 18 percent larger than the 1949 crop and has been exceeded only in 1945 and 1946. Inspections indicate movement is running considerably ahead of the slow marketings from that State during the fall of 1949. In the southern part of Alabama, dry weather did not reduce yields as much as expected earlier in the season.

1950	399.6	1,847.1	562.8	1,618	1,747	341,036	357 797

Acreage partially duplicated.

^{2/} Asparagus, snap beans, lima beans, beets, cabbage, sweet corn, cucumbers, peas, pimientos, spinach, and tomatoes.

^{3/} Artichokes, asparagus, snap beans, lima beans, beets, cabbage, cantaloups, (including honeydews, honeyballs, and miscellaneous melons), carrots, cauliflower, celery, cucumbers, eggplant, lettuce; onions, peas, peppers, spinach, tomatoes, and watermelons grown commercially for market. Excludes farm gardens and most market gardens.

^{4/} Totals are for crops shown in preceding columns, omitting alfalfa seed, red clover seed, alsike clover seed, and lespedeza seed. These are included in the count of crops, but the acreage is not included because mostly duplicated in the hay acreage; the acreage of peanut hay, largely duplicated in peanuts picked and threshed, has been deducted. Other crops not included are sweet corn for market, some of the less important commercial truck crops (75,800 acres in 1950), farm gardens, most market gardens, hops, spelt, hemp, velvet beans, various legumes and other crops harvested by livestock, minor crops, and fruits and nuts. The acreages shown include some crops harvested in succession from the same land.

^{5/} Preceding column plus estimates of acreages planted, and not harvested, as shown in separate table of acreage losses.

vested, thus in for cotton inc crop losses ch age in some dr peas.3/Exclude	shown for winter wheat represent the acres sown in the preceding fall and not har notified the considerable land subsequently planted to other crops. The acreages shown lude more than 10 million acres plowed under in 1933. The totals do not show total iefly because of the large acreage of hay land which produced nothing except pastury seasons. 2/Rice, buckwheat, potatoes, sweetpotatoes, sugar beets, and dry field s grains cut for hay.

1/ Season begins with the bloom of the year shown and ends with the completion of harvest the Following year. In California picking usually extends from about Oct. 1 to Dec. 31 of the following year. In other States the season begins about Oct. 1 and ends in early summer, except for Florida limes, harvest of which usually starts about April 1. Estimates of production include fruit consumed on farms, sold locally, and used for manufacturing purposes, as well as that shipped. Fruit ripened on the trees but destroyed by freezing or stormsprior to picking is not included. 2/ For economic abandonment, see page 88. 3/ The indicated production for 1950 is based on reported prospects on December 1. 4/ Includes small quantities of tangerines. 5/ Net content of box varies. In Calif. and Arizona the approximate average for oranges is 77 lb. and grapefruit 65 lb. in the Desert Valleys; 68 lb. for California grapefruit in other areas; in Florida and other States, oranges, including tangerines, 90 lb. and grapefruit 80 lb.; California lemons. 79 lb.; Florida limes, 80 lb. 6/ In California and Arizona, Navels and Miscellaneous.

figures.

2/ The drying ratio in California is about 21/2 lb: of fresh fruit to 1 lb. dried; in Washington and Oregon, from 3 to 4 fresh to 1 dried.

Excludes quantities used on farms where grown,

Short-time average. Dry basis.

For economic abandonment, see page 88. These quantities are not included in utilization

Includes small quantities frozen in some years prior to 1941.
